ORIGINAL ARTICLES

FRAGMENTARY COMMENTS ON SOME OF THE PRINCIPAL METHODS OF OPERATION FOR "STONE IN THE BLADDER."

With Special Reference to Allarton's Method, Also in Combination with Lithotripsy, Urethro-Lithotripsy, Urethrotomia Lithotriptica, Including Besides Critical Remarks Upon the Discussion of the Progress Made in Lithotripsy and "Lithotomy" at the Late International Medical Congress held in London, England, and divers other subjects comprising the Urinary Organs.

BY M. SCHUPPERT, M.D., OF NEW ORLEANS, LA.

Of the present essay, though written over two years ago, I have had so far no inducement to make any important alterations of its contents, and will therefore offer it for whatever it may be worth.

In conveying my views on some of the main operative methods for the removal of vesical calculi, I was induced principally by the success I had met, with Allarton's urethrotomy, and the failure on the other hand of the International Medical Congress held at London, England, to give us a better method. It was the disappointment I felt from the discussion on the subject by that phenomenal gathering of professional celebrities, a concourse of genius and talent more prodigious than the world had probably ever seen before, which led to my critical remarks. Amongst the chief subjects selected by that Congress for discussion, the operation for "stone in the bladder" occupied a prominent place. Considering the presence of so many illustrious representatives of the profession, it most assuredly could not be said it was claiming too much, in expecting a final settlement of the subject in question, either accepting and approving what so far had been accomplished as satisfactory, or giving us instead new and better methods. Nevertheless, if we except that single shining proof of American ingenuity, Bigelow's method of lithotripsy, the result of the discussion of that deliberating assembly on the subject in question was a most barren one, and in respect of the diverse methods of cystotomy, far from conclusive. The congressional success had evidently suffered from the preponderating influence of the address of its presiding officer.

Exploring the field of the operative technic of the diverse methods of the operation for stone, I met with many existing deficiencies which wanted reform, but it was most the unjust dereliction of Allarton's urethrotomy, that long since reconstructed, though repeatedly mistaken, or, converted and improperly disregarded operation, which induced me, and without prejudice, to again assign to the front rank that same *pærineal median urethrotomy of Allarton,* a method which comprises in itself all the elements rendering an operation valuable, and which if combined with lithotripsy will fullfil every demand required to establish its superiority. Such a method deserves more than a superficial mentioning. Its position is secured, whether the designation or name I have applied, is adopted or improved upon.

The essay will also comprise an analysis of opinions, delivered on the subject in question by members of the International Congress, which will enlist some interest. I think it, moreover, proper to call attention to the importance of some of the supplementary contributions, all more or less intimately connected with the urinary organs, and which will lay open a number of sins of omission and commission. The rear of the essay will be brought up by an anomaly of the "*homo sapiens,*" but with the ingenium gone astray, an unique in surgical history.

Before entering the main subject, I think it but proper to call attention here to two frequently used terms, which seem to me erroneously selected, or misapplied, and one of them even unorthographically written, which terms call for correction, according to the truism that "an hundred years of *wrong* do not constitute a single day of *right.*" No educated linguist will coin words or terms which etymologically misrepresent an idea he wishes to inculcate. Thus is the term "*lithotomy*" used promiscuously and erroneously for the operation of stone, in which the bladder or another part of the urinary tract, is incised, whilst the etymology of the word implies instead "*cutting the stone,*" it being derived from *Λίϑος*, the stone, and *Γέμνεῖν*, to cut. It is therefore synonymous with lithotripsy, or lithotrity, from *Λίδος* and *Γριβῖν*, fatur, *Τρίψω*, to cut to pieces. We ought therefore to supplant *lithotomy* by the two terms, *cystotomy* and *urethrotomy*, cutting either the bladder, or, the urethra, for obtaining the object of freeing the bladder from stone.

The other correction comprises the term "*perinæum,*" or, "*perineal,*" which ought to be written *pærineum* and *pærineal*, in being derived from πγ̃ρχ, or, πγ̃ρις the bag, and νδιω, I dwell, designating the region between the ischiatic tuberosities, the anus and the scrotum Properly, therefore, it can only be applied in the *male*, and not in the *female* If we want a term applicable to both, to the male as well as the female, we ought to exchange the word for the term *interfemineum*, *interfemineal*, a word not derived, as some might believe, from *femina*, the woman, but which originates from *femen*, or *femur*, oris *Interfemineum* would then signify the region between the thighs, and could be used in both sexes, in the male as well as the female In many of the classical works of Livius, Lucretius, and even Plinius and Celsus, says the great anatomist Hyrtl, we meet with that term *femen* in the sense here given Thus *feminalia* and *tibialia* were used by the Romans to signify bandages around thighs and legs, as our garters So much for some corrections which speak for themselves, and ought to be adopted by every progressive mind

Among the diverse operative methods for "stone in the bladder" we might best discriminate between operations without using the knife and such where the knife has to be employed, or operations by which the stone is removed through the natural passages, with or without a previous crushing, and such in which the removal of the stone is obtained by an artificial passage which can be accomplished either by incising the urethra, or the bladder Finally we may distinguish a third method, a combination of the first two of cystotomy, or urethrotomy, with subsequent lithotripsy, of which the latter, no doubt, would be the preferable one, and which I have designated with *urethrotomia lithotriptica* (lithotriptic urethrotomy)

We would then obtain the following scheme

A *Lithotripsy*
B *Cystotomy*
1 Lateral C (pærineal lateral C)
2 Epicystotomy (E suprapubica, or sectioalta)
3 Proctocystotomy (C recto-vesicalis)
C *Urethrotomy*
1 Pærineal median Ur (Allarton's method)
2 Bi-lateral, Dupuytren's
3 Procto-urethrotomy (recto-median Ur)
D *Urethrotomia lithotriptica* *Lithotriptic urethrotomy*

It is known that the operation for stone was formerly in the hands of a certain class of specialists, called "*stone cutters*," and that it was not before the 18th century that the operation became common in good surgery The disease indicates the operation *per se*, but the selection of the method for removing the stone depends on a variety of conditions and circumstances Thus we have the nature and size of the stone, complications of the disease, state of the kidneys, of the bladder, the urethra, the urine, the age of the patient, etc, which will greatly influence the selection of the method and the time of the operation The earlier the operation is performed the better, but this is often thwarted by ignorance and failure to detect the disease Regarding the *Statistics*, I have but a few words to say Certain writers on the subject, as Sir H Thompson, of England, and others, have stated that in all cases of stone in the bladder, lithotripsy ought to be preferred "for humanity's sake" John E Erichson, the illustrious President of the late International Medical Congress, a surgeon who usually commands confidence when he makes a direct, definite statement, is of the same opinion Still his statistical mortuary reports of the two operations of cystotomy and lithotripsy, in his last edition of "Science and Art of Surgery," deserve but little credit When here Erichson says "that 4/5 of all cases in the adult were proper subjects for lithotripsy," we know very well that he based his dictum upon our known mortuary lists But if we look a little closer into these same statistical records, and the material which served in their composition, we find that the majority of those cases, which underwent the operation of lithotripsy were so called "*picked* or *selected cases*" We have therefore merely the statistics of *selected cases* before us Comparing them with the results obtained by cystotomy and urethrotomy indiscriminately chosen, and of cases operated upon often under the most unfavorable conditions, is an improper and unjustifiable proceeding

Another, and not less important point, consists in the doubts which have been uttered with regard to the accuracy of the statements of certain known specialists of our days, upon which these statistics were mainly based Thus Civiale, the known professional lithotritist of France, who once incited so great a stir amongst professional men, gives the deaths from that operation performed by him as 1 in 42 2, or, of 591 operations he will have lost but 14 (!) while the most skillful operators, in England for instance, had a mortality rate of 1 in 7 9, or, at the most favorable, 1 in 10 That such statements as those of Civiale, in the face of the known insalubrity and bad sanitary condition of the Parisian hospitals, and their equally known enormous death-rate in capital operations at Civiale's time, deserve but little credit, is obvious But to observe Civiale's statements sink to the lowest ebb of credulity, we need only compare them with those of his more candid and trustworthy cotemporary fellow citizen and colleague, the great and honest Malgaigne, whose estimates of mortality in those same hospitals of Paris were given by him as 1 in 4, and in private practice as 1 in 8 So much for statistics serving as a basis in giving preference, or superiority of the one method over the other here mentioned

Selection of the method of operation —Lithotripsy —The promise with lithotripsy totally to remove "the decomposable debris" and the "*sharp fragments*" of the crushed calculus by the aspirator of Clover, or the highly priced evacuating apparatus of Bigelow are no doubt great improvements in the operation of lithotripsy, still they should not induce us to exclusively swear allegiance to that method The danger arising from a wound so much feared, for instance, in the presence of a chronic cystitis, has lost its weight and importance under the proper administration of a thorough asepsis, or antisepsis

Lithotripsy, except if combined with urethrotomy, has lost with me a great deal of its charm, even in the hands of the ingenious Bigelow, since I have experienced the serviceable boon of *Allarton's perineal median urethrotomy* It may commonly be considered a great mistake to advance unqualified claims in favor of the superiority of a select method and give to it an unexceptional preference In surgical practice, as well as in medicine generally, it ought to be recognized as one of the elementary truths and main principles *in no disease to let one and the same treatment preponderate to the exclusion of all others* The same disease may under different circumstances require an entirely different treatment A thorough acquaintance with the diverse methods, in addition to the character of the ailment, and of the proper selection of the operation adapted to the special case, are what the surgeon ought to know and which will offer the best chances for success The surgeon, on the contrary, who thinks to appropriate every case to his favorite hobby, must turn out at the end as complete a failure as the physician committed to the same dogma The adoption of a method of operation is controlled by experience, its propriety in most instances is confirmed or refuted by its general results, and it is not uncommon that by experience views are gained widely different from those which at a former period had been recognized as true and proper The question of the propriety of performing in a given case either cystotomy, lithotripsy, or urethrotomy, or the two latter combined, is often difficult to decide, on account of the various dispositions, the condition of the individual case, or on part of the operator

One of the main objections raised by some surgeons against lithotripsy has been the fear that fragments of the crushed calculus might remain in the bladder, causing there, it was thought, *recidives* But others proved that such fear was absurd, and the irritation or pain produced by such sharp fragments would be early disclosed by the irritable bladder, so that where no complaint by the patient was uttered, all of the debris had been discharged If these views were correct, we would have to come to the conclusion that in cases where a new calculus had formed, different causes must have prevailed in its formation And indeed, micro chemical investigations about the origin of the calculus disease have confirmed that view to be the correct one Recidives happening after cystotomy, as well as after lithotripsy, have further supported this opinion, that other causes had to exist to explain the origin of a calculus We have been informed by reliable authority that in forty cases of cystotomy and lithotripsy such recidives happened twice, and in both cases after cystotomy In one instance it was a second, in the other a third time that the operation had been performed in the same individual Another referee told us " that in a case the lateral section had been performed three times—twice in the old cicatrix, without meeting any of the difficulties mentioned here, and two and three years after the first operation, when the recidives happened The stones in this case consisted of phosphates of ammonia, magnesia and lime, with urate of ammonia" (Prof Grube, of Charcow) It seems, then, that the probability of such recidives may exist wherever the patient continues to live under the same influences which were the cause of the formation of the calculus at the first time, though as to the nature of the influences we still remain in the dark

But besides the empty fear for recidives from such remaining fragments, there exists still a more serious consequence from them, though overlooked by most surgeons, or erroneously considered of little consequence Of this later

The operation of *lithotripsy*, at present known as "*Bigelow's method*," is no doubt one of the most brilliant conceptions of human genius and of modern surgery From the first efforts of its performance by Gruithousen in 1813 with his lithotripion and the three branched instrument (trois branches) of Leroy d'Etiolles in 1822, Jacobson's articulated stonebreaker in 1829, and Hurteloup's epoch-making lithotriptor, or " percuteur courbé a marteau " in 1832, improved by Mercier, and still in use, until Bigelow's new armamentarium, with which the history of the operative technic of lithotripsy will in all probability be closed In that history it seems we have a new proof of the old observation of how slowly and gradually the mind becomes educated till it finally arrives at a grand conception, the beginning of which usually being the most complicated and intricate before it finally obtains a simple solution

The operation of lithotripsy is one of extraordinary delicacy, affording great skill and dexterity Equally so has ample expertness and care to be employed in the manufacture of the instruments here used, and none of them ought to be taken in use before its strength and mettle have been fully tried, since a distortion or a break might cause much mischief In the printed Transactions of the mentioned International Congress, we find an exact description of Bigelow's method, called *Lithotopaxy*, and also the drawings of the diverse instruments belonging to his armamentarium The method of Bigelow has been proclaimed "as beyond further improvement, it being more than even an elaborate advancement, having reversed what so far had been based upon well-established principles, and it ought to be recognized as an entirely new operation " "The crushing of the calculus and the subsequent removal of its fragments *in one sitting*, to facilitate which the instruments have been altered, increased in size and improved in composition, and the results obtained by Bigelow himself, by Otis, Thompson in England, and others, all write in the confirmation of the characteristics of Bigelow's triumphant revolutionary method as a great advancement in surgical practice "

Far removed as I am from bickering or hair-splitting, yet I cannot agree with Dr Teevan's international peroration in which he called the old method " the great opprobrium, that often neither killed nor cured , which removed the stone but failed to cure the patient," and " that such was not the case with Bigelow's operation, which would not be followed by a chronic cystitis, with its consecutive phosphatic deposits " Singular that to some men it appears often so difficult, be it in their eulogies or censures, to mete out an even-handed justice

What we have just heard here from Dr Teevan is not quite " the whole truth " The doctor took the colors rather too thick I have known surgeons, for instance the late Dr Stilling, one of the most skillful and lucky operators, and a specialist in lithotripsy to boot, who often extended the number of sittings to eight, twelve, and in several cases to even twenty (a great number of his cases were published in the *Berliner Klinik*) before he discharged his patients, and most of them perfectly cured In none of his cases did we hear that a chronic cystitis followed the operation, nor was it mentioned as having already existed Neither is the removal of all fragments in one sitting so absolute a necessity, nor does Bigelow's method require it

Chronic cystitis frequently complicated with pyelitis (pyelonephritis) is one of those obstinate and unfortunately resisting diseases, in which lithotripsy, and were it even Bigelow's method, is of some service or advantage, which would render it preferable to urethrotomy or cystotomy Yet lithotripsy might even be contraindicated, if the disease, for instance, should be complicated with an enlarged prostate, or with a great irritability of the bladder, where chills and a high fever might ensue Cutting such a hypertrophied prostate would, on the contrary, have a beneficial influence, the gland getting thereby smaller, or attaining its normal size, provided that no alkalinity of the urine existed, and a proper aseptic treatment followed The easier access to the bladder, permitting a frequent washing out with the aseptic liquids, a more thorough drainage, preventing any accumulation of urine, are all so well known beneficial factors in an existing chronic cystitis, that the question of a supremacy of urethrotomy or cystotomy cannot for a moment be doubted Dr Teevan considering as detrimental already a simple introduction and examination of the bladder with the catheter, in the presence of a chronic cystitis, how much more should he not avoid an operation with enlarged instruments, as the sound or percuteur, and such even during a protracted time of from one to three hours, after Bigelow's own statement? The examination of a bladder, if executed in a tender manner with aseptic instruments and the patient narcotized, ought not to alarm Dr Teevan, since it is a totally harmless operation if properly handled And when Dr Teevan, in an old man with chronic cystitis and an enlarged prostate, hopes to accomplish more by lithotripsy, *followed* by external urethrotomy, a combination, the doctor prides himself on being the happy inventor of, I do not feel jealousy, nor do I grudge him *his* invention, neither will it induce me to cease giving preference to the "pærineal median urethrotomy," *followed*, if necessary, by lithotripsy, saving thereby time, labor, and also consistency

Besides Dr Teevan we met with other brilliant lights in that International Medical Congress, who have been to us a source of instruction and not less of amusement Of great interest are thus the "*Congressional debates about lithotrity and lithotomy, their comparative value and of the progress which had been made in the two operations*"

Decorum might require us to listen first to what the presiding officer had to say I therefore call attention first to the distinguished surgeon John E Erichsen, who at the same time delivered the inaugural address to the "*International Surgical Council*," composed of four vice-presidents and secretaries (all English), besides forty-one Englishmen, with twenty-five outsiders Small as was the number of those foreign to English soil, it was sufficiently balanced by genius and talent Among the eight important subjects laid down for discussion was, as third "*The advances, if any, which of late had been made in lithotrity and lithotomy*"

Regarding "lithotomy" *Erichsen* saw "much of change, possibly of novelty, but not so certainly anything of real progress" Erichsen put the question boldly "Have we indeed advanced a single step, either in the *perfection* or in the *result* of that operation, since the days of Cheselden, of Martineau, or of Crosse, not to mention the names of more recent but equally illustrious surgeons and successful operators? They have certainly not been very encouraging in their results and can scarcely claim to be considered in the light of an advance on the lateral operation in skillful hands"

Yet Erichsen admitted that the methods of "lithotomy" might deserve this consideration—"that possibly in some forms of calculus and in certain conditions of the urinary organs a wise eclecticism might be exercised in the choice of one or the other of them" In lithotripsy he was willing to admit that a great and real advance had *probably* been made," yea, he graciously declared that this great revolution had been effected by American *enterprise* and *skill*, that Bigelow's operation had completely changed the aspect of lithotripsy, and that here a fertile field had been opened for deliberation in what cases Bigelow's operation might safely be used? also the ultimate result upon the bladder and the kidneys a prolonged intravesical instrumentation would have" And again, "that further information would be needed as to the comparative advantage of one or more sittings, and the more important question of determining the life and future comfort of the patient

The discussion which hereon ensued centered almost exclusively in the operation of Bigelow, while most of the propounded questions remained unanswered, instead of which those participating in the discussion gave us their views, with which they had probably intended beforehand to entertain the assembly

From what is to be perceived of that inaugural address, as well as from the latest edition of his elaborate work on surgery, I do not believe John E Erichsen always to be that unbiased judge whose dictum ought to carry great weight if not conviction with it When Erichsen stated that in "lithotomy" we had *not* made any real progress, that we had not advanced a single step, either in the perfection or in the result of that operation since the days of Cheselden, not to mention the names of more recent illustrious surgeons and successful operators," I should like to inquire what kind of progress he was looking for and where the deficiencies came in? To these questions I consider myself the more entitled since Erichsen in that same address had remarked, and very properly "that there could not always be new fields for conquest by the knife" But when he then continues "The revived median, its combination with lithotrity, the supra pubic, whether done antiseptically or not, have certainly not been very encouraging in their results, and can scarcely claim to be considered in the light of an advance on the lateral operation in skillful hands," I again have to inquire after the source from which he felt empowered to form and express such an unfavorable, unjust and untrue opinion? When the mortality of a certain operation compares well with the most favored one, or even surpasses it, be it in the percentage of cures, the manner and security of execution, the smaller number of instruments used, or in the time of recovery, I think it unjust in a high degree to raise such complaints When science has established such a variety of means for the cure of a disease as in "the operation for stone," any modest surgeon ought to be thankful for such "*richesse*," and fertility of genius, instead of uttering so unqualified a condemnation of a general want of progress If in mentioning "the revived median operation" Erichsen referred to Allarton's method, I have even to increase my protest against such unjust and undeserved aspersion of so excellent and unrivalled an operation Altogether, Erichsen's criticisms of the missing advance and progress in "lithotomy" have been unsound, contradictory and ungenerous, and most so have those surgeons unjustly been touched by it, who endeavored to cultivate a method so improperly neglected, misconstrued and falsely colored, as the pærineal median urethrotomy of Allarton, the obtained results of which will compare favorably with any other operation in the whole area of surgical practice

Now let us hear another typical Englishman, Sir H Thompson, "the greatest living operator for stone" as he is called, who is said to have performed the greatest number of such operations—beyond 800 Thompson stated "that he had operated after Bigelow's method in ninety cases, and that most of the old men operated upon had been of an average age of 60 years, and had lost of these ninety cases only three by death, whilst eighty-seven recovered Ten cases he operated on during that time with the lateral section, of which number four had died, and one operated after Allarton's method, who had recovered The calculi in the average weighed twenty grams, (five drachms) The majority of these cases, he stated, would not have admitted uncommon large instruments The *smaller* the instruments, he thought, the *better* would be the results, and the earlier the operation was performed the better, since then every calculus might be removed in one sitting" Of the complicated cases he did not give an opinion Of the various methods of "lithotomy" worth mentioning, he named "the *lateral section*, the *sectio alta*, the *pærineal median* and the *recto-vesicalis*" He gave the advice "to select either lithotrity or the lateral section, and if necessary also combined with crushing the calculus" Such a combination he thought "under some circumstances preferable and less dangerous than removing the calculus entire" From the result he himself obtained with that lateral section, a mortality of 40 per cent, he certainly could not very much recommend it In lithotrity he advised to dilate well the urethra and neck of the bladder The percuteur when entered through the urethra ought to be surrounded by an Indian rubber tube The bladder ought partially to be filled with water to prevent the catching of parts of it, and the pelvis might be lifted to better keep the injected liquid in the bladder The evacuation of the bladder from the fragments through a catheter, might it be ever so large, would nevertheless require *often repeated crushings*, a proceeding much more dangerous than an additional wound in the pærineal part of the urethra through which to remove the fragments A cut into the enlarged prostate could be no objection, since by giving additional room such would be rather beneficial to the patient A catheter introduced through the whole urethra would besides give pain, while if entered through a pærineal wound it would be well borne

I have faithfully recorded here all Sir Thompson mentioned in the congressional debates appertaining to the matter under discussion There is not much of new material of which we were not already aware, chiefly that the operation of lithotrity would be more successful under the application of smaller-sized catheters, a step evidently backwards from Bigelow's method Not less remarkable is the lightning celerity with which Sir Thompson is stated to have performed his lithotritic operations, many in five minutes! When we consider all the precautions as given by himself, the catching of the stone—frequently the most difficult and time-consuming part—the crushing and removing all of the fragments, and probably through a small catheter, which he preferred, and with the assurance that none of the débris be left behind, continuing, according to his own statement, in the average but from six to nine minutes, (!) such passes my comprehension, and gives an idea of the wonderful dexterity of that wonderful man, and not less is his success to be wondered at, when we consider the danger which, under certain circumstances, a wound made by the percuteur, or even the smallest fragments remaining in the bladder may cause, under the total neglect of all antiseptic injections or washing out the bladder And this the more so, since according to his own statement death *once* (?) followed, the real cause of which remained unknown to him "Of chronic cystitis he met but a few cases, and which took him a long time to cure" Of the use of antiseptics he did not say a word, neither did he give us the number of accidents he met with, he only stated that "occasionally phosphates did again form" Herewith we can take leave of Sir H Thompson, turning to our countryman, the ingenious *Bigelow* He, we are aware, removed the fragments through the whole length of the urethral canal, by his ingeniously constructed instruments His method called litholopaxy has, by general consent, been called a "*question of apparatus*" Bigelow's essential instrument is the catheter, or sound of from 21 to 31 mm circumference, with a large orifice, eye, while of the catheters commonly in use, it may well be said that 'they delayed the progress of lithotripsy for sixty years " Bigelow states that "even the most minute piece of a crushed stone left behind might become the nucleus of a new calculus " But there exists still a greater danger, of which later To prevent fragments from going back during the evacuating process, Bigelow constructed his evacuating apparatus, an improvement of Clover's, for washing out the bladder as well as for sounding after the smallest fragments This instrument consists of a sound with a valve, or strainer, and a stiff bulb, all, according to him, very important parts for a successful lithotritic operation The sound with the evacuator has been named "the key to modern lithotripsy " But when Bigelow said "it would take time to decide if modern lithotrity was not better than lithotomy," that question strikes me as being paradoxical, since such a time will probably never arrive There may be more cases fit for the operation of litotripsy, but that does not render it superior to cutting, to urethrotomy, or cystotomy Both methods may in time have their places better assigned than at present, but never will even modern "litholopaxy" displace either urethrotomy or cystotomy, just as there may arrive cases unfavorable for any operation at all Neither do I assent when Bigelow thinks that "lithotripsy did not need any further statistics even in small stones," since complications may happen with small as well as large ones Worthless as our present statistics are, the preference given to the knife in small children with small stones, instead of using the lithotriptor, will, I believe, be generally supported In cases complicated with chronic cystitis and pyelitis, may the patients be old or young, the stones large or small, the patient will fare better under the selection of a cutting operation than by lithotripsy Besides, it may be difficult for the practical surgeon to rid himself of the traditional preference for the knife All of which will certainly delay the final verdict, which Bigelow thinks so near, if not already decided, so that he feels empowered to utter the dictum, "that the patient will encounter less risk with modern lithotrity," and that he does not know "any indication when lithotomy should peremptorily be decided upon "

The weight of the after-treatment that the bladder should be well drained and the needed rest be given, which the knife will better accomplish, that alone ought to have made Bigelow hesitate to give such a categorical decision His statement that lithotrity was not as skilfully executed by the general surgeon as "lithotomy," I most willingly admit, though want of skill is certainly not a point for a general recommendation, but then it should rather be in a preference for urethrotomy or cystotomy

When Bigelow further states that "no secondary hæmorrhage could happen with lithotrity," I have to call his attention to recorded facts, and that even so expert and skillful a surgeon as Sir H Thompson lost a case in consequence of it, according to his own statement Regarding Bigelow's assertion that "there was not a grave wound in a diseased prostate, communicating perhaps with putrid catarrh of the urinary tract," I regret to have equally to protest against it, as not corresponding with stubborn facts

Amongst 120 lithotriptic cases performed by American and English surgeons—counted in 1881—after Bigelow's method and with a death-rate of but six cases, or 5 per cent, excellent as that result would be, yet it cannot be taken exclusively as a criterion in judging the value of the method The death rate, so uncertain a factor in itself, since we seldom, if ever, become acquainted with all the unfavorable results, is not by far the most important factor in judging the capacity of a method It was just the high death-rate in cases complicated with cystitis and pyelitis, that lithotripsy, notwithstanding the success of some surgeons, was condemned and relinquished by the majority of the profession, when Bigelow appeared with his speedy and complete removal of the irritating and poisonous detritus, and by his revolutionary proceeding in the reconstruction of the instruments, not merely saved the operation from a total annihilation, but elevated it anew into the position of one of the foremost operations for the removal of a vesical calculus

The drawback the new operation of litholopaxy suffers from, preventing it from a more frequent adoption, mostly so in localities where stone in the bladder belongs to the rare diseases, is the high price of the costly instruments—$40—which are in no comparison with the few and cheap instruments the operation of urethrotomy requires This, with the skill required in the performance of litholopaxy, deters the general surgeon from its selection and preference, while to perform urethrotomy, or even cystotomy, unfortunately every tyro in the profession considers himself at least an Astley Cooper, a Velpeau or a Dieffenbach

(TO BE CONTINUED)

INCONTINENCE OF URINE IN CHILDREN

BY SAMUEL S ADAMS, A M, M D,

LECTURER ON THE DISEASES OF CHILDREN, MEDICAL DEPARTMENT UNIVERSITY OF GEORGETOWN, D C

Read in Section on Diseases of Children of American Medical Association, May, 1884

How a subject of as much importance should have so long escaped presentation and discussion before the American Medical Association is surprising, but the fact exists that it never has been presented to this body, and for that reason I have chosen it

There is not much importance attached to the history of the disease With the assistance of Drs Kolipinski and McArdle, of this city, I have examined all the literature on the subject from 1784 to the present, including articles in German, French, Italian and Spanish In 1784 Mitchell wrote on the disease as clearly as any subsequent author, and its pathology was as well understood then as now The tendency at that time was to let it alone with a hope that puberty would restore the function of the bladder

From birth the child instinctively voids its urine, and we take it for granted that the act is reflex But with the evolution of the teeth, speech begins, intelligence is developing, and we expect the will to control the sphincter vesicæ The rule is that about the eighteenth month the child is taught to exercise complete control over the sphincter If after this age the urine is passed involuntarily the tendency is to attribute the disgusting act rather to carelessness than to a pathological state, which to my mind is an injustice to the child From observation and the supervision over children of every condition of life I am loath to accept this conclusion and am proud to state that all the cases which have come under my observation have had specific causes, and were not the effects of laziness So, believing as I do in a pathological state, it delights me to attempt this defence of the long-abused unfortunate

Many a child has been repeatedly and unmercifully punished for wetting his clothes or bed, in the face of repeated protestations that he could not help it The disease and punishment go on together until the patient becomes such an object of disgust to himself and his family that they are impelled to seek professional advice Then the parents learn that they have been chastising their child, perhaps for years, for a fault which was the result of disease and therefore uncontrollable, when they would have quickly resented a just punishment if administered by some one else for a real fault less offensive in its character

Again, there are others who, while they believe the act involuntary, will let it run on for years with the hope that education and the inculcation of habits of cleanliness will effect a cure, or that their only hope for relief is in the establishment of puberty

The child instinctively becomes neat, and seeks the proper time and place to empty its bladder, and I am unwilling to admit that it ever deliberately soils its clothes after it has once been taught to use the vessel None of the brute creation will lie in their urine if they are not tied or penned, then why do we attribute this practice in the rational being to laziness? Simply because some are not able, by a careless and superficial examination, to find the cause, and well knowing that their reputations will be at stake if they do not account for the act, they too often condemn the helpless child to daily floggings There must be a pathological condition to account for an act that makes nature an abhorrence to herself, and it is our duty to seek diligently for it, remove it, and thus transmute the filthy child into the cleanly

But in too many cases the act continues untreated, in spite of punishments and the jeers of companions, until well-marked physical changes take place The child, bright and cheerful by nature, soon loses his vivacity, shrinks from the presence of his companions, becomes morose and spiteful, pale and haggard, restless and nervous, will not look you in the face, and with chin depressed and upper lids drooping, presents, indeed, a striking likeness to the onanist

We generally find the disease divided into three varieties In the first class the subjects suffer from a constant dribbling of urine day and night This variety is infrequent, and when found it is usually associated with some serious pathological state I have met with but two cases of this kind, in boys about eight years of age, who for several years had been unable to retain their water Examination revealed a vesical calculus in each case, which being removed, the function of the bladder became normal

A second class comprises those whose incontinence is intermittent in character, and occurs in the day as well as at night We find that in this class the urine is retained for a short time during the day when the desire to void comes, but before the child reaches a convenient place the sphincter is overcome, and the poor child is powerless to stop the flow This is the form usually met with in the girl In fact the histories of those I have seen have been that the girls would suddenly be taken with a desire to urinate, while in school or on the street, but before they could reach a closet the power of control gave way The cause in these cases was found to be vulvitis or urethritis, as a result of the irritation from ascarides in the vagina

But the third class is the one that interests us most because of its frequency in both sexes, its nocturnal character, its possible concealment for years, and the promptness with which it yields to treatment It is the children of this class who are so frequently punished for bed-wetting when they are as powerless to control the sphincter during the night as are those of the two preceding classes during the day They may, and usually do urinate before retiring, and yet, about midnight, during a profound sleep, the urine is passed again, or it may be that the night is passed without the accident, but just before rising in the morning the contents of a full bladder are involuntarily set free Patients of this class generally dream of urinating In the boys of this class urination takes place during erection of the penis Again we meet with cases where the cause is obscure, but, nevertheless, the nocturnal incontinence occasionally takes place In these patients I attribute the accident to causes that favor a perfectly physiological process in the adult We well know that late suppers, rich food, wines, certain positions during repose, profound sleep, amorous or lascivious dreams, and many such causes produce a nocturnal pollution in the adult, and I am convinced that the same causes excite a similar irritation in the child, but instead of the seminal discharge, the physiological process of which is not yet established, the bladder is emptied In each instance the discharge is the result of a conservative process of nature to relieve the irritation Indeed, this theory seems the more plausible because in many instances the nocturnal bed-wetting goes on undisturbed until the full establishment of the sexual functions, when the enuresis is superseded by nocturnal pollutions This theory is also tenable because most of the remedies which cure the adult of his complaint very quickly relieve the the child of its

The disease is more frequent than the statistics of hospitals would seem to indicate, for the greater number of cases go untreated until a spontaneous cure is reached The probability is, it is not always differentiated and recorded as a distinct disease, since in the statistics I have examined it seems to have occurred only 46 times in 15,169 children treated at the Children's Hospital, D C , five times in 2,058 at the Children's Hospital of Boston, and four times in 2,034 at the Children's Hospital of Philadelphia, or 55 times in 19,261 sick children

It most frequently exists in children between 8 and 12 years, but may occur at any time between 2 years and puberty It is common in both sexes, white and black

Trousseau was the first to trace a relationship between incontinence and epilepsy, claiming that in rare instances one succeeded the other and that these histories always pointed to the transmission of one of the neuroses

Some writers claim that there is a reflex relation between hip disease and nocturnal incontinence, but the records of the Children's Hospital of this city, where a great many cases of hip disease are treated annually, do not accord with the statement

The following cases include some of each of the three classes

Case I Ernest P , 4 years, W , was admitted to the service of Dr F A Ashford at the Children's Hospital, D C , during my term as resident physician, March 11, 1870 He had had difficulty in retaining and passing urine for several years There was now constant dribbling March 16 a calculus weighing 110 grains was removed by the lateral operation and the patient was soon after discharged cured

This child had been regularly punished for several years while the stone was the constant irritant and its removal effected a speedy cure

Case II Sarah C , 15 years, C , was admitted to the service of Dr Busey, in the same institution, Oct 28, 1876 She had had constant dribbling of urine for seven years She was treated with the tincture of belladonna and was discharged cured Dec 4, 1876

In such cases as this it is not always easy to determine the pathological condition Usually atony or paralysis of the bladder, enlarged prostate, or stricture of the urethra is present

Case III Frank C , 7 years, W , was admitted to Dr Ashford's service April 19, 1879 He had had dysuria for some time As soon as he desired to urinate he had to run to the closet to avoid wetting his clothes Wet the bed at night Blood passed in urine at times April 24 a calculus weighing 175 grains was, with great difficulty, removed by the lateral operation, and the patient was soon after discharged cured

Case IV Henry S , 4 years, C was admitted to the same service Sept 12, 1871 For two years he had had difficulty in retaining his water and pain on micturition A calculus weighing fourteen grains was removed by the lateral operation, and the patient was discharged cured

Case V L M , twenty-two months, W M , was admitted to the same service Aug 4, 1873 Had frequent desire to urinate, at times painful, sometimes involuntary, urine offensive A calculus weighing fifty-two grains was removed by the lateral operation Aug 11, and the patient was discharged cured

Case VI S T , 8 years, C M , was admitted to the same service Aug 5, 1880 He had difficulty in retaining his water and sometimes wet his bed Examination revealed phimosis Circumcision was performed Aug 21, and the boy was soon after discharged cured

Case VII C W , 4 years, C M , was admitted to the same service March 13, 1882 He had had for some time frequent and difficult urination, at times involuntary Circumcision was performed and the boy cured

Case VIII James S , 4 years, white On the 19th of March, 1884, Dr Busey invited me to assist in circumcising this boy From birth the little fellow had been accustomed to pass his water frequently, but after straining for several minutes he would become tired and cease trying, apparently before the bladder was emptied Dr Busey's attention was called to this condition, and examination revealed an elongated prepuce, with an opening about the size of a knitting-needle The patient at this time was pale, languid, thin, restless, slept at short intervals during the night, retained his water only a short time He, being etherized, was circumcised as described later on The adhesions to the glans were so firm that it required a longer time than usual to break them up He soon recovered from the operation, and has not had any difficulty about urination since Three weeks after the operation Dr Busey informed me that I would hardly recognize the child. He had become fat, rosy and cheerful

It may be claimed by some that this case is not properly classed, as there was no actual incontinence But if it is admitted that in a perfectly healthy child of his age the urine should be retained three or four hours, then an uncontrollable desire to pass water at shorter intervals being shown, it would seem to approximate incontinence and hence this classification Although I cannot state positively, still I venture the assertion that when the desire to urinate came, if he had not hurried to a convenient place he would have soiled his linen

Case IX Mary W , 4 years, colored Was admitted to Dr Busey's service April 19, 1871 She had had incontinence, and intense pain on micturition for one week, the incontinence mostly at night She was treated with tincture of belladonna, and discharged cured May 17

Case X W H , 12 years W M Was admitted to the same service September 3 1879 Four years before he had had measles, from that time he had had incontinence day and night He was put on the belladonna treatment, and discharged cured March 6

Case XI Guy P , 11 years, W Was admitted to the same service September 3, 1879 He would generally hold his water until the bladder became distended, when he lost control over the sphincter He was improving rapidly under the belladonna, when his parents removed him without the consent of the attending physician

Case XII Nellie C , 8 years, W Was admitted to the same service May 9, 1882 She had had incontinence day and night for six years She was given the stigma of maize and belladonna, and was discharged cured June 11

Case XIII Alice L , 4 years, W Was brought to me for an excessive leucorrhœa and inability to retain her water for any length of time At short intervals she would run for the closet, but before reaching it she would lose control over the bladder Examination showed the presence of ascarides in the rectum and vagina She was given santonin internally, and enemata of aloes and milk, and was speedily cured

Sometimes we meet with cases of incontinence with high colored, acid and offensive urine when the administration of bicarbonate of potassium will quickly effect a cure

Finally, another class is met with where there is an adherent prepuce, with a collection of smegma behind the corona In such cases breaking up the adhesions and cleansing the part will generally effect a cure

Case XIV Ida B , 13 years, C , was admitted to Dr Busey's service April 12, 1883 She had had nocturnal incontinence for two years She was treated with belladonna and discharged cured June 8, 1883

Case XV Fred R , 3 years, W , was taken with balanitis in November, 1883 Upon examining him I found an elongated prepuce with an opening about large enough to admit an ordinary darning needle, from which was pouring a profuse purulent discharge The inflammation was believed to be due to the phimosis, and I advised circumcision At this time I questioned the mother as to whether he was the subject of nocturnal enuresis, and learned that he sometimes wet the bed, but was in the habit of calling her three or four times during the night to put him on the chamber On the 24th of November, with the assistance of Dr McArdle, circumcision was performed The mucous membrane was adherent as far as the meatus, and a large quantity of smegma was behind the corona In ten days the patient was discharged and up to date (May, 1884) has not wet his bed, holds his water well during the day, and rarely has to be taken up at night

Case XVI Charles O , 8 years W Four years prior to operating his father informed me that the boy was in the habit of wetting the bed at least once, and often several times, every night At that time I did not examine the boy, but accepted the father's statement that the prepuce was long, incapable of being retracted, and with an opening large enough to admit a small probe Owing to the father's prejudice against anæsthetics, and my unwillingness to operate without them, the trouble continued unchecked I refused to advise the administration of drugs, stating that in my judgment the incontinence would never be cured without circumcision In November, 1883, he had measles and was under my care When convalescent and in good condition I proposed circumcision, and obtained the consent of the parents as well as the patient—the latter being anxious to be cured On the 2nd of December, with the assistance of Dr McArdle, circumcision was performed While the night before the operation the patient voided his urine three times during sleep, since then he has only done so twice, at long intervals On these occasions the incontinence was attributed to salty diet and the taking of large quantities of water

At my request Dr H D Fry, of this city, gave me the following details of a case that came under his observation It properly belongs to class I

Case XVII "Sept 13, 1882, I was requested by Dr J H Davidson, of Montgomery Co , Md , to perform circumcision upon a patient of his who was suffering from incontinence of urine, due, apparently, to an elongated prepuce

"The patient was fifteen and a half years of age, and fairly well grown The penis was small and undeveloped, and extending from the end of the organ was a long snout-like projection of preputial tissue, which could not be retracted over the glans penis His mother gave the following history of the case Until the age of five years he was not unlike other children as regards both his general condition and the appearance of his *privates* At this time his penis was broken out with poison oak and the prepuce could then be drawn back in order to attend to the dressing of the part After his recovery the glans penis could not be exposed

"When about eleven years of age the parts became sore again, and from this time he had no control over the discharge of urine His general health declined, complexion was bad, complained of pains in his side, and became nervous and irritable His manner at school was so different from that of other boys that his teacher's attention was called to his actions, and he spoke to the boy's parents and advised them to have something done with him

"Such was the state of affairs at the time of the operation, and it had existed about four and a half years

"I removed the redundant tissue back to the corona, broke away some adhesions that existed, and left the case with the request that no medicinal treatment should be employed I wished to see the effect of the operation *per se*

"April 28, 1884, the boy's mother wrote the following report 'After the operation he had no fever, slept well without opiates, and suffered little pain There was little or no suppuration In a week he left his bed, and in a month returned to school His general health since has improved slowly, is less irritable, complexion better, and retains his urine ' "

In the few cases of occasional nocturnal incontinence the cause may be an over-loaded stomach or bowel, intestinal worms, hip disease, adherent prepuce, or amorous or lascivious dreams

I myself do not doubt that in cases of phymosis, the nocturnal incontinence is due to reflex irritation In some cases the irritant is the smegma behind the corona which keeps up a constant excitation During the day the will is powerful enough to overcome the action of the spinal centre presiding over urination, while at night the will is asleep and the reflex reaches its maximum In other cases, owing to the contracted orifice of the prepuce, the bladder becomes tired from prolonged expulsive efforts and relaxes curred only 46 times in 15,169 children treated at the Children's Hospital, D C , five times in 2,058 at the Children's Hospital of Boston, and four times in 2,034 at the Children's Hospital of Philadelphia, or 55 times in 19,261 sick children

It most frequently exists in children between 8 and 12 years, but may occur at any time between 2 years and puberty It is common in both sexes, white and black

At my request Dr H D Fry, of this city, gave me the following details of a case that came under his observation It properly belongs to class I

Case XVII "Sept 13, 1882, I was requested by Dr J H Davidson, of Montgomery Co , Md , to perform circumcision upon a patient of his who was suffering from incontinence of urine, due, apparently, to an elongated prepuce

"The patient was fifteen and a half years of age, and fairly well grown The penis was small and undeveloped, and extending from the end of the organ was a long snout-like projection of preputial tissue, which could not be retracted over the glans penis His mother gave the following history of the case Until the age of five years he was not unlike other children as regards both his general condition and the appearance of his *privates* At this time his penis was broken out with poison oak and the prepuce could then be drawn back in order to attend to the dressing of the part After his recovery the glans penis could not be exposed

"When about eleven years of age the parts became sore again, and from this time he had no control over the discharge of urine His general health declined, complexion was bad, complained of pains in his side, and became nervous and irritable His manner at school was so different from that of other boys that his teacher's attention was called to his actions, and he spoke to the boy's parents and advised them to have something done with him

"Such was the state of affairs at the time of the operation, and it had existed about four and a half years

"I removed the redundant tissue back to the corona, broke away some adhesions that existed, and left the case with the request that no medicinal treatment should be employed I wished to see the effect of the operation *per se*

"April 28, 1884, the boy's mother wrote the following report 'After the operation he had no fever, slept well without opiates, and suffered little pain There was little or no suppuration In a week he left his bed, and in a month returned to school His general health since has improved slowly, is less irritable, complexion better, and retains his urine ' "

In the few cases of occasional nocturnal incontinence the cause may be an over-loaded stomach or bowel, intestinal worms, hip disease, adherent prepuce, or amorous or lascivious dreams

I myself do not doubt that in cases of phymosis, the nocturnal incontinence is due to reflex irritation In some cases the irritant is the smegma behind the corona which keeps up a constant excitation During the day the will is powerful enough to overcome the action of the spinal centre presiding over urination, while at night the will is asleep and the reflex reaches its maximum In other cases, owing to the contracted orifice of the prepuce, the bladder becomes tired from prolonged expulsive efforts and relaxes before it is emptied. During the day frequent micturition is observed, but the bladder is not emptied; at night the desire to urinate is just as frequent, but the *will* is asleep and the spinal centre responds to the irritant by involuntary micturition.

To determine the pathological condition is not always an easy matter. Atony of the sphincter vesicæ, or spasm of the detrusor urinæ may be the cause. The controlling power over the sphincter, which is largely reflex, may, by the influence of the will, prevent the escape of urine during the day, but at night, when the will is asleep, this power is relaxed, and the consequence is involuntary micturition regardless of cerebration.

As I do not admit that incontinence is frequently the offshoot of fear or laziness, of course I hold that moral suasion and corporal punishment are not efficient correctives, and equally of course I contend that in most cases the indicated procedure is either remedial or operative.

It would be more interesting than instructive to examine the literature of the internal remedies which have been successful in these cases. Nearly every drug in the materia medica has been tried with equal success, if we are to credit the books. Drugs physiologically and chemically incompatible have been combined and success claimed for them. Accepting *the theory of a want of tonicity in the muscular walls* of the bladder, some have used remedies that should have aggravated the trouble and yet have claimed a perfect cure. In such cases the results were probably accidental, and most likely were brought about by nature in spite of the treatment.

Leonardi and others extol chloral, but others have failed to derive any benefit from its use. It acts by allaying the reflex irritability in the cord. I do not approve of the use of this drug with children, certainly not except with the utmost caution. Owing to the variability in strength of the preparation, and the uncertainty of its physiological action, as well as the individual idiosyncrasies, it must, in my opinion, be regarded as one of the most dangerous and uncertain remedies in common use.

The bromides take foremost rank in the treatment of those cases in which an exalted nervous condition can alone account for the incontinuence. They should be given in large doses at bedtime.

But belladonna is the remedy *par excellence* in the treatment of those cases believed to be associated with a tonic spasm of the bladder. One of its physiological actions is to relax the tonic contraction of the involuntary muscular fibres. The muscles of the bladder being of this class, when the atropia in the urine comes in contact with the walls of the bladder it allays irritability and relaxes spasm. In order to derive benefit from the drug it should be given in large doses at bedtime, which should be increased, drop by drop, daily, until improvement results or its physiological effects are obtained. It must be borne in mind that children will bear much larger proportional doses than adults. I speak in the highest terms of this drug because, as will be seen from the foregoing cases, it alone produced beneficial results in about four weeks.[1]

If there is a relaxation of the sphincter vesicæ or paresis of the muscles of the bladder, strychnia is indicated. But as I have never seen a case of this kind I have had no experience with it.

If the patients are puny or in ill health we would naturally expect better results by improving the general health while we are administering remedies.

Experience has taught me that the best success attends those patients who are treated in hospitals. In these institutions the diet of the child can be regulated, and many advantages gained in treatment. Parents will insist and believe that the physician's instructions are carried out in full; but they forget the sympathizing friends about the house who think the child unduly restricted, and who are, therefore, willing and ready to cater to its whims. For this reason it has been my custom to advise children to be placed in the hospital. If the patient can be fully controlled, success will quickly attend the treatment indicated.

In order to make statistics of operative procedures valuable, the use of remedies should be suspended. If we operate, then the operation should stand upon its own merits, and not be embarrassed by drugs. After a circumcision, if belladonna is given how can we tell which means effected a cure? In the cases above reported as operated on, nothing but soporifics were given.

I do not advocate circumcision as the certainly indicated remedy in *all* cases, nor do I believe that every boy who has incontinence, with an elongated prepuce, should be compelled to undergo the operation. If the prepuce cannot be retracted, then I would advise operating; and while sometimes the opening in the prepuce is large enough, yet it cannot be retracted owing to adhesions. In such cases, if these adhesions are broken up favorable results will follow.

I prefer to perform the operation of circumcision in the following manner. The prepuce is drawn forward, and Henry's clamp tightly applied; the end of the prepuce is then cut off with scissors, and the clamp left on the stump for several minutes to check bleeding; a director is then pushed along the upper surface of the glans, and the mucous membrane divided beyond the corona. The membrane is then turned back to meet the retracted skin, and made fast by five silk sutures. In about ten days the patient is well. I remove only that part of the mucous membrane that is cut off with the end of the prepuce, for by leaving a long membrane it can be turned back and thereby hide the cicatrix, which is a source of mortification to many parents. In cases VIII, XV, and XVI, there is nothing to attract the attention to circumcised organs. One objection to the operation is that the glans will be left uncovered, and that it destroys to some extent the sensitiveness of the organ. If this were true it would in many cases prove a great blessing, but, unfortunately, it is not true Another objection is that the beauty of the organ is destroyed, whereas, in fact, if the circumcision is neatly done the penis presents a far better appearance than it does with a redundant foreskin

---

[1] NOTE.—In all of Dr. Busey's cases the belladonna was given at night and increased, drop by drop, daily, until the desired effect was produced.

From the foregoing cases, which have invariably been attended with complete success, without the administration of a drop of medicine, is it to be wondered at that I so strongly favor circumcision ?

Some have advised forcibly stretching the contracted prepuce—a process both tedious and unsatisfactory

Teevan, a British writer, advocates slitting the meatus, which he thinks is too small in most children with incontinence As I have not seen any cases requiring the operation, I must accept his statement that benefit was derived from it

There is one other kind of treatment discussed and recommended in the books, that may be called the mechanical

Many here present, I dare say, have been called to treat an œdematous prepuce caused by tying a string around the penis to prevent bed-wetting Perhaps some little fellow, after frequent thrashings, has finally, in sheer desperation, conceived the idea of eluding the lash by tying up the escape-pipe He may have missed the chastisement, but he paid dearly for the immunity

Corrigan, apparently a writer of note in Great Britain, deliberately and strongly advocates hermetically sealing the prepuce with collodion He stretches the prepuce and forms a pouch, into which the collodion is poured, solidifies, and thereby prevents the escape of urine !

Compression of the membranous portion of the urethra by a pad, and packing the vagina have also enthusiastic devotees !

Knotted towels, spiked belts and other uncomfortable rigging to prevent the child from lying on its back have also received their share of commendation

It seems hardly necessary to comment on these various mechanical methods of treatment, since they seem to evince a hopeless ignorance of the etiology of the disease, and are not only valueless but actually harmful

The bibliography of this subject has been very carefully examined, with the courteous and efficient aid of Drs Fletcher and Wise of the Surgeon General's Office, U S A , and I believe the following is a measurably complete list

HINTS ON THE USE OF DRAINAGE TUBES

BY W L GETZ, M D, MARSHALLTOWN, IOWA

Some months ago we had occasion to evacuate a pelvic abscess, and use a drainage tube as a means of thorough drainage Not having at hand at the time a regular drainage tube, we constructed one out of a piece of plain (small size) rubber tubing After being in the opening for several days we desired to replace it by another tube, we attempted to remove it, found that the opening in the tissues through which the tube had passed had contracted so as to hold tightly the tube, and although we made but slight traction, anticipating the possibility of the tube's breaking, to our extreme discomfort and dissatisfaction, we soon realized that our anticipations were realities, a portion of the tube, an inch in length, remaining within the pelvic cavity

We succeeded in removing it by dilating the opening through which the tube was passed, then introducing a small blunt hook, we succeeded in drawing the piece of tube into position, so that it was easily grasped by a pair of forceps and extracted, much to our satisfaction, and with a vow that in the future we shall select with *caution* our *material for drainage tubes*

A hint on the removal of tubes and also upon their introduction may not be out of order here under circumstances as above described, where the tissues firmly hold the tube, we should adopt the plan of inserting within the tube a dilator of some kind with which to dilate the tissues before we attempt to withdraw the tube

As a satisfactory method of introducing drainage tubes, we have found that where a trocar-canula were necessary to evacuate the contents of a cyst or an abscess, that by taking the precaution to use a canula a trifle larger than the drainage tube to be used, the latter could be conveniently passed through the canula into position and then the canula withdrawn

A NEW SURGICAL POCKET CASE

BY J H PARKINSON, M D, SACRAMENTO, CAL

Read before the Sacramento Society for Medical Improvement, Dec 16 1884

To propose a new surgical pocket case may seem a very unnecessary proceeding, yet a glance at the catalogue of any large instrument maker shows that the best form has so far not been attained, for in no class of appliances, except perhaps the obstetric forceps, is the variety as great Its name implies that it contains such instruments as may be required in minor surgery, arranged in the smallest bulk, so as to be readily carried with the minimum of inconvenience In looking over the different models one must be struck by their singular unfitness for this object The instruments are often clumsy and ill adapted for their purposes, the knives arranged in combinations dissimilar in ability, and articles are included which in practice are almost useless No better instance of this can be cited than the British Army regulation case, with its portable hypodermic syringe, a weapon even in skilful hands of perilous accuracy It is not alone that the contents shall be of the best and most improved manufacture, selected with a view to general utility and emergency, but that the case itself shall be of such dimensions as will by its portability ensure its always being at hand Most manufacturers in an effort at compactness make their cases thick and short, so that when closed they are almost cylindrical This is one of the most awkward forms conceivable for the pocket, it is not so much the length or breadth of a case which is objectionable as its thickness, and just in this essential particular existing models, otherwise practically useful, fall short The first great step in the improvement of this most important adjunct to the practitioner was the invention of movable blades and universal handles, which has made it possible to carry a large number of cutting instruments in a confined space Availing themselves of this, Tiemann & Co and Charriere have produced very serviceable cases, while that of Professor Dugas, though not after the same model, is perhaps more useful than either These which may be taken as the best types of their kind, are well suited for the office or carriage, but certainly not for the pocket of any garment save an " ulster "

Recognizing the disadvantages of existing models, and knowing the difficulties in the way I have proceeded slowly, practically testing any new idea before including it in the general plan I think I have now a genuine "surgical pocket case," which, while it contains every instrument required in daily practice, is available in such emergencies as are at any time liable to occur The instruments are of the best manufacture, combined where it was possible to do so without sacrificing effectiveness The case is of a shape and material to render it adaptable to the pocket, and at the same time of sufficient strength to stand wear and tear and protect its contents

The instruments, twenty-five in all, comprise two shell handles, each with a universal and Tiemann's catch to take blades, etc, containing respectively a small, sharp, pointed, curved, bistoury and tenotome Fitting into these handles are a metacarpal saw, a knife, cutting edge 2⅝ inches in length, two scalpels, medium and small, a curved bistoury probe pointed, and a curved needle, a grooved exploring needle, Weir's combined lancet and vaccinator, a caustic case, also containing an eye spud for foreign bodies, a trocar and canula, an artery forceps, grooved to carry needle, slide catch, a bullet forceps, Tiemann's patent jaw action, open rings and catch, scissors, one sharp, one probe point open rings, a combined tenaculum and aneurism needle, a director with end for separating tissues, a catheter, metallic, flexible, 9 inches long, a small eye probe, silver, Nélaton's probe, steel flexible, ordinary silver probe tapped to receive Nelaton's portion of silver probe with eye and *porte meche* tapped at one end and attachable to either of the foregoing, three steel pins for acupressure, some silver ones, smaller, needles, curved and straight, silver wire, silk suture and ligature assorted

Taking the instruments in the above order The handles are neatly made of the best tortoise shell, and contain in one end a strong tenotome and a short curved bistoury sharp pointed, secured with a slide catch when open These two knives for general purposes are required more frequently than any others As it is necessary to have two handles for the extra blades, and only possible to utilize one end for them, the advantage of having these two knives always prepared for use, and where they are taking up what would otherwise be waste space, is obvious Tiemann's patent catch is so fully described elsewhere that I need not dwell upon it, except to add that it is perfect in its effective simplicity The metacarpal saw is of the ordinary pattern The long bistoury, which measures 2⅝ inches on its cutting edge, is shaped like the ordinary amputating knife, which makes it much stronger than the usual model The medium sized scalpel is after Charriere's, the small scalpel has a round edge The curved bistoury probe pointed is full length, and by means of two strips of adhesive plaster can be converted into a hernia knife The grooved exploring needle is gilt, which will not stain or tarnish on contact with purulent fluids The curved needle will be found useful where sutures have to be inserted deeply in fleshy parts Weir's scarifier and lancet is a perfect little instrument, though of course carrying with it the objections urged against any permanent vaccinator The caustic case is of aluminum, and contains in its other end an eye spud This particular pattern was suggested by Dr W E Briggs as being safer in the hands of the non specialist than most forms The trocar and canula is of medium size, permitting it to be also used for exploring purposes The shape of the handle was adopted to save space in packing The bullet forceps, being contained in a pocket-case, is of necessity short, but will often be found of sufficient length It is useful, as suggested by Dr F H Brown (Boston *Medical and Surgical Journal*), in removing foreign bodies from the ear and nose By an ingenious arrangement the jaws have a separate action, and can be divaricated independent of the handles quite widely without distending the passage or sinus A small catch makes the instrument self gripping, and provides a useful dressing forceps The scissors have one probe and one sharp point, this is to be preferred to the blunt pointed variety The relative length of the blades to the handles, ⅓ to ⅔, by providing good leverage enables them to cut firmly and to the point Like the bullet forceps, they are provided with open rings to economize space The combined aneurism needle and tenaculum is of steel, and, I trust, more generally serviceable than those we usually find in pocket cases The curve of the needle is Charriere's, and that of the tenaculum an average of several models, permitting it to rest comfortably on the index finger at an angle of forty-five degrees when tying The director of steel has an end like that of the ordinary scalpel handle for separating tissues, and as this is often required when the director is in use, it will be found a very handy combination The catheter, in two pieces, is Gross' metallic flexible, fitted so that the parts slide over each other, it is conical pointed, which will often facilitate introduction The probes consist of a small double-ended silver one, the ordinary silver probe made extra heavy, and provided with a female screw at one end, Nelaton's probe, made of flexible steel, a useful modification of Dr C This has a male screw cut in one end, an eyed probe, silver, with slot cut to use as a porte meche, the other end furnished with a male screw These, when fitted together, form a long silver bullet probe, and a Nelaton's probe with reversible silver end The case is of Morocco leather, unlined except where the blades rest, silk being there used in preference to velvet as less likely to take the dust It measures when closed 5¼ inches in length, 3 inches in breadth, and ¾ of an inch in thickness, and fastens with a long flap, bringing the lock on the edge of the case, a position less likely to injure the pocket It is twofold, with one pocket The caustic case is carried inside the flap, the catheter on the hinge One side is devoted to the instruments, the other, lined with silk, takes the extra blades, a piece of undressed kid being fastened under the covering flaps, which meet, so as to effectually protect them

As will be seen, many of the instruments and models are those now in use All I claim is originality in the selection and arrangement Messrs Geo Tiemann & Co have rendered me most valuable assistance by many hints and suggestions, the result of their extensive experience Too much credit could not be given them for designing and making several of the instruments from very imperfect descriptions and sketches

MEDICAL PROGRESS.

SURGERY.

UNION OF DIVIDED NERVES BY SPLICING —A L Rawa publishes (*Centralbl f Chir*, Glasgow *M J*) the results of a large series of experiments on nerve suture by a new method It often happens that divided nerves stitched together by either the direct or the perineurotic method are torn apart again, especially if they have to be stretched to any extent to make good loss of nerve tissue Rawa's experiments were made upon animals, and in these the two ends of the divided nerves were laid side by side, riding sufficiently to allow of a single ligature being tied around them In some of the cases the experiment was varied by drawing out the two ends a little, turning up the two ends at right angles to the nerve, and whipping them together in that position. In a few of the animals more than one nerve of a limb was divided, and the peripheral end of the one nerve tied to the central end of the other, or the peripheral ends of two nerves to the central end of one.

In all cases it was found that in course of time the function of the divided nerves was restored, but that it took longer time (from six to twenty months) to restore it. The author gives details of the macroscopic and microscopic appearances of the nerves at various stages.

Rawa believes this method will be found useful in cases where a considerable portion of a nerve has been destroyed by an injury, or has to be removed during an operation, or where sutures have been tried and have torn through the tissues. Again where, as in operations for removal of tumors, etc., several nerves have to be divided, or part of a plexus removed, it may be possible to splice remaining portions of nerves together in such a way as to avoid loss of motion in the muscles supplied.

CORROSIVE SUBLIMATE AS A SURGICAL DRESSING.—Sir Joseph Lister delivered an address on this subject before the Medical Society of London. He has had recently several instances of results deviating from what he considered the normal type in aseptic wounds; in one instance a fatal result occurred from a form of spurious septicæmia, such as he had not seen for many a year. This was the only fatal case he had had, but other cases with delayed union and pus formation had occurred, undoubtedly of a septic character, that is to say, dependent upon the development of micro organism, although in none of the cases was there any offensive smell. Lately he had been using eucalyptus gauze; and owing to the great volatility of the eucalyptus oil, he had come to think that so much of it volatilised during the manufacture and drying of the gauze as to lessen materially its protective power. Formerly he had used dammar gum as holding the oil more securely than ordinary resin, but dammar was very expensive. After some further trials with resin, he had felt justified in substituting the cheaper material; recently, however, the results had proved far from satisfactory. He found, further, that the manufacturer had deviated from his instructions, and had left the gauze exposed to the air for a longer period than formerly, and it was to be feared that much of the eucalyptus oil had evaporated away. He had little doubt that the untoward results he had just referred to were due to imperfections in the manufacture and quality of the gauze he had been using. Volatile substances doubtless had many advantages, but also very many disadvantages; thus dressings became less and less antiseptic the longer they were worn, and they were also much at the mercy of the manufacturer. He pointed out the capabilities of some non-volatile substances, such as salicylic acid and iodoform. As to corrosive sublimate, Dr. Koch had shown the remarkable germicide action which the sublimate exerted on all forms of low organisms, including the bacillus anthracis, the spores of which were among the most resistant. Koch had ascertained that a solution of sublimate, 1–20,000, was adequate to absolutely destroy the vitality of the spores of the bacillus anthracis. The wood-wool dressing of Germany was a very unwieldy form of dressing, on account of the bulk required. Lister has found that corrosive sublimate formed with serum of the blood a compound which retained the antiseptic properties of the corrosive sublimate. Under such circumstances, it was not an albuminate of mercury in a chemical sense, but an albuminate of the compound corrosive sublimate; and this was a matter of great interest to the surgeon, for it was not only innocuous as regards the skin, but thoroughly antiseptic in its properties. Thus the discharges from a wound, in passing through a sublimate dressing, became associated with, but not precipitated by, the contained sublimate, and the sublimate in this way was rendered very much milder in its action, and could, therefore, be applied in a more concentrated form. With blood serum, 1 part in 70, or in 50, or in 30, it was perfectly amalgamated, and when dried gave off no deposit or crystalline separation whatever; it was free from smell, and applied to the skin was quite unirritating. He had found it thoroughly trustworthy as an antiseptic, and quite equal to freshly prepared carbolic gauze. French charpie, made of old rags, might be saturated with the solution, and would then form a very efficient and cheap dressing. If serum were treated with a certain proportion of sublimate, not sufficient to make it solid, it could be kept for an indefinite time. Perhaps one day sublimated serum might come to be an article of commerce, to be used in hospital and private practice. Perhaps even, dried and powdered, it might come to be mixed with vaseline, and used as an ointment, or be scattered over wounds as iodoform powder was used at the present time.

PERFORATION OF THE BOWEL FROM BIMANUAL EXAMINATION OF THE UTERUS.—Dr. E. Schwartz, of Halle, relates (*Centralbl. fur Gyn.*, Glasgow *Med. Jour.*) an interesting case of where, in a woman 46 years of age, he made a bimanual examination of a uterus containing a fibroid tumor as large as a child's head. For some years he had kept down menorrhagia by the use of the curette and astringent injections, but ascites appeared, and the patient became cachectic. Fearing malignant degeneration, he determined to examine the interior of the uterus after dilatation of the cervix by a laminaria tent. Before inserting the tent, a one in a thousand watery solution of corrosive sublimate was injected into the uterus. Immediately thereafter the patient became sick, and was taken to bed without anything further being done. An hour afterwards she had a severe rigor, and the pulse rose to 140. There was severe retching and diarrhœa, with the passage of 18 ounces of blood from the rectum. The abdomen became greatly swollen, and death occurred from collapse in 40 hours. The diagnosis made during life was that of poisoning from corrosive sublimate, due to the solution finding its way into the peritoneal cavity through some diseased part of the uterine wall. At the autopsy the uterus was found intact. Pus, blood and fecal matters were found in the abdominal cavity, and also a pea-sized perforation of the bowel a little above the ileo cæcal valve Many old adhesions existed, and a fragment on the posterior wall of the uterus was observed to correspond to the perforation in the bowel One of the kidneys was examined for mercury, but none was found in it It thus appeared that death had resulted from the tearing of the adhesion binding the posterior wall of the fundus to the bowel lying behind, and this most probably happened (when the fundus was drawn forwards) during the bimanual examination, made immediately before the injection of the corrosive sublimate solution

INTRODUCTION AND EXTRACTION OF NEEDLES — M Despris, in a lecture which he delivered at La Charite (*Gazette Medicale, Med Times*) made some interesting observations A young woman, striking a table with the palm of her hand, thrust a needle into the base of her middle finger and this, striking against the first phalanx, broke and became fixed there When seen two days afterwards, the fragment of needle had completely disappeared amidst the inflamed tissues On pressing at the base of the middle finger, however, a foreign body, pressure on which occasioned pain, could be felt An incision was made at this point, and a fragment of needle, measuring 1½ centimetres, removed by the forceps Here the incision was justified by the fact that the foreign body was firmly fixed The subject of a second case was a young woman, into whose breast a needle was driven obliquely by a blow, and entirely disappeared under the skin Guided by the patient the presence of the needle could be ascertained, but in this case an incision for its removal would be improper, for the integuments of the breast are so mobile that an incision made in the skin would not correspond to the foreign body The presence of the needle having been exactly determined, we should seize it in its length and make pressure on its two ends At one of these we may perceive a slight cracking sound, and here the patient also feels a sharper pain than elsewhere, and this is the point of the needle If we now press firmly upon the other end this point will be forced through the integument and can then be seized with a forceps An incision should never be made except when the body is fixed in the tissues, as in the first case One caution must be borne in mind, and that is, we should never attempt an extraction on the mere statement of the patient that a needle is present in the tissues, and when we are unable to verify its presence, for sometimes persons declare that they have needles in their tissues when they have not, or when we are consulted the needle may have already migrated to another part of the body, this migration sometimes taking place very rapidly

MEDICINE.

PERCEPTION OF SOUND IN AUSCULTATION (*The Stethescope as a Conductor of Sound*)—Haupt, in the *Aerzlishes Intelligenzblate* (*Medical Chronicle*), shows that while the tubular shape of the stethescope may have led the unwary in the opinion that it conducts sound like a speaking tube, the vibrations started by heart and lungs are incompetent to impart audible vibrations to a light medium like air, but can do so to a denser medium like wood or the solid skull, which may be placed in contact with the chest wall Hence it is merely the wood, and not the air in the tubular passage of the stethescope, which conducts sound, and conduction is more perfect the larger the surfaces of the instrument applied to the ear and chest wall At the same time an ordinary stethescope has certain properties of a resonator (1) by virtue of its being an open tube, (2) by virtue of its wide ear-plates, which may act on occasion as a sounding board As a hollow resonator the stethescope is a very weak instrument, being limited in its range, as a rule, to the fundamental tone and the first overtone By means of the ear-plate as a sound-board it is somewhat more efficient, and we can sometimes detect chest murmurs while the ear is held at some distance from the instrument, without touching it *But both these aids are lost as we use the instrument,* for the tube no longer acts as a resonator when we block up both ends of it, and the vibrations of the ear-plate are checked by applying the ear to it In short, the bore of the stethescope is quite superfluous, and a solid "hearing staff," with a wide ear piece and a wide chest-piece, is the theoretically perfect instrument

THE COAGULATION OF THE BLOOD —Dr Richard Norris considers this subject at some length in his address as President of the Birmingham Philosophical Society (*Birmingham Medical Review*) As the result of his investigations he affirms that changes in the fugitive discs, by which term he includes the advanced lymph discs, the colorless discs, and all the intermediate forms up to the diffused edged corpuscles, and also the free nuclei of the white corpuscles, are competent to cause the formation of fibrine without the aid of the hypothesis that the liquid of the blood holds *in* solution fibrinogen and fibrinoplastin which unite under the influence of a ferment to form fibrine At the outset he accepts the truth of Rindfleisch's statement, that "recent fibrine is invisible under the microscope, owing to its great homogeneity and transparency " The entire process of coagulation, as it occurs in the blood, may be thus summarized

1 The young discs are insoluble in the liquor sanguinis or in ¾ per cent salt solution

2 Without any apparent change, save that which induces adhesiveness and viscosity, they become converted into fibres

3 These fibres, and the young discs which give rise to them, appear to possess the properties of *plasmine*, for they are soluble in a sufficiently dilute salt solution, say ¼ per cent, as seen when the corpuscles or fibres absorb vapor in a bubble space

4 After a time these fibres become no longer soluble in ¼ per cent salt solution, or in aqueous vapor, and this insolubility comes on by continued contact with the liquid of the blood

5 This insolubility, which represents the transmu-

tation of plasmine into fibrine, is probably affected by water, which acts by decomposing plasmine and dissolving up the products of this decomposition, viz , fibrino-plastine and ferment

The fundamental error which vitiates all the experiments made to prove the presence of fibrinogen and fibrino plastine is the erroneous belief that by ordinary filtration or subsidence the whole of the morphological elements of the blood can be got rid of 1 Absolutely pure liquor sanguinis obtained in this way does not coagulate, nor do any fibrils form in it 2 When a saturated solution of common salt is added to it, and evaporation allowed to take place till crystalization of the salt occurs, no precipitate is formed, so that *plasmine* does not really exist in the true liquid of the blood 3 Finally, plasma obtained in the ordinary manner by subsidence, if submitted to capillary filtration, may be separated from the substance which induces coagulation The same is true of lymph

The whole of the morphological elements can be removed from any kind of blood by diluting it into ¾ per cent solution of sodium chloride at 0° C sufficiently to destroy the viscosity caused by the presence of albumen, and maintaining the freezing temperature till subsidence of the capsules has occurred Under these circumstances we find that the red discs sink first and take the lower place, the intermediate partially colored discs next, and the colorless last Above these is a brilliantly clear liquid Now where does coagulation occur? Not throughout the liquid, as it should do if the coagulable material were in solution, but in the upper layer of corpuscles, while the clear supernatant liquid, if removed by a pipette and placed in a separate vessel, shows no disposition whatever to coagulate This experiment demonstrates, in the most unequivocal manner, that the material which coagulates is under the influence of gravity and can not, therefore, be in solution

TRANSMISSION OF PHTHISIS —At the late meeting of the Hygienic Congress at the Hague, two important communications were read on this subject (*Progres Medical, Medical Times*) In the first of these Prof Corradi, of Pavia, draws the following conclusions 1 That the contagion of pulmonary phthisis is possible 2 Prolonged cohabitation is one of the principal conditions of its occurrence 3 Debility and all causes which diminish the power of organic resistance render it more easy 4 The possibility of transmission through the medium of clothing, goods, etc , has not been sufficiently proved 5 It is also doubtful whether the milk or flesh of tuberculous animals can give rise to the transmission, especially after culinary preparations 6 That, at present, regulation of cohabitation is the only prophylactic measure that can be had recourse to 7 Investigations should be continued in different countries, with the aid of a uniform formula

The other paper was a report from M Vallin, on the " Danger of Alimentation by Means of the Flesh and Milk of Tuberculous Animals," of which these are the conclusions 1 The tuberculosis of animals is specifically identical with human tuberculosis 2 It has been proved that the ingestion of raw tuberculous matters may engender tuberculosis 3 The injection under the skin or into the peritoneum of the blood or muscular juices of phthisical animals, is capable of determining phthisis 4 The ingestion of the raw flesh of phthisical animals is capable, in certain cases, of transmitting the disease, and especially abdominal tuberculosis 5 The inoculability of tubercle is not destroyed, except by a notably higher temperature than that attained by the central portions of roasted meats 6 The milk of phthisical cows may transmit tuberculosis, and is especially dangerous when the mammary glands are tuberculous 7 Boiled tuberculous milk is harmless 8 In order to guard against all danger, we should, at all events, provisionally prohibit the use of meat of animals, the subjects of confirmed generalized tuberculosis, with commencing emaciation 9 The habit of eating underdone meats should be discouraged, and, as a matter of security, milk should always be boiled 10 Attempts should be made to diminish the frequency of tuberculosis in animals by choice in breeding, improved stalling, isolation of infected animals, disinfection of contaminated stalls, etc 11 Tuberculosis of horned cattle should be ranged among contagious diseases affecting them, and submitted to the laws applicable to these 12 Assurance societies against tuberculous cattle should be encouraged, in order to indemnify the proprietors for losses from this cause

PEPTONISATION —An important contribution to the physiology of albumins has recently appeared from the pen of Herr Chandelon It is well known that peroxide of hydrogen is decomposed with the evolution of oxygen in the presence of fibrin and organized tissue as well as of several metals and oxides, and it has generally been stated that this dissociation takes place without the albuminoids or metals undergoing any change No evolution of oxygen occurs when other organic substances are brought into contact with the peroxide of hydrogen Herr Chandelon suspected that in this latter case there might be a reaction, though it was not perceptible because the oxygen was used up in oxidizing the organic matter In order to test this suspicion, egg albumen was suspended in water and exposed to the action of nascent peroxide of hydrogen At first sight there was no result, for neither leucin nor tyrosin was detected Nevertheless, it was observed that the albumen had undergone some change, in that the volume of the precipitate produced by boiling the mixture gradually diminished, whilst the liquid after separation of the coagulum by filtration gave upon treatment with alcohol a copious precipitate, which, upon being redissolved in water, gave all the reactions of an albuminoid substance Further investigation left no doubt that the albumen had, partly at least, been converted into peptone, it was therefore of interest to study the reaction more closely, to isolate and identify the intermediate products Herr Chandelon found that peroxide of hydrogen in the nascent state peptonises egg albumen, and peptonisation may be considered a phenomenon of hydration, an opinion that is supported by the formation of peptone from albumen by reagents capable of fixing water, such as dilute acids, alkalies, etc., and the reconversion of peptone into albumen by a dehydrating material like acetic anhydride. It is suggested that the albumen (anhydride) gives up an atom of oxygen to the peroxide (H_2O_2), just as oxide of silver does, and that the two groups that had been united by the oxygen then combine with two hydroxyls. The conversion takes place by the same process as in digestion with peptic ferments. The author puts forward the hypothesis that the digestive ferments promote digestion by the production of peroxide of hydrogen.—*Lancet*.

THE CONDITION OF THE FUNDUS OCULI IN INSANE INDIVIDUALS.—Drs. J. Wigglesworth and T. H. Bickerton have published, in two recent numbers of *Brain*, the results of investigations at the Rainhill Asylum extending over a period of two and a half years. There were 313 patients satisfactorily examined, of these 66 were general paralytics and 247 non-paralytics. Among the latter (mania, 82 cases; melancholia, 49; mental stupor, 2; dementia, 61; epilepsy, 48; imbecility without epilepsy, 5). The optic discs and main retinal vessels were perfectly normal in 83 per cent., and among the remaining 17 per cent. the changes were in some cases doubtful, and in some others were clearly due to causes, such as Bright's disease, which had no direct connection with the patients' lunacy. Among the general paralytics, decided changes were present in 23 per cent., and if to these cases be added a few more in which the existence of change was doubtful, the percentage rises to 35. They come to the following conclusions:

1. That in insanity proper (including all forms *other than general paralysis*) changes in the fundus oculi are found in a small minority of cases, but that when allowance is made for changes depending upon associated constitutional conditions, errors of refraction, etc. the number of cases in which a connection between the mental (cerebral) state, and the accompanying change in the fundus oculi, can be so much as suspected, is very small.
2. As a corollary, that in insanity proper no connection can be traced between the condition of the fundus oculi and the patient's mental state.
3. That in the majority of cases of "General Paralysis of the Insane," the fundus oculi presents a perfectly healthy appearance.
4. That in a minority of cases clear and precise lesions are found.
5. That these lesions fall into two main classes, the one tending in the direction of slight neuritis, the other in that of atrophy.
6. That in the former class the affection declares itself as a hyperæmia of the discs, the edges being softened and indistinct, so that in some cases they can be traced with difficulty or not at all; and that these conditions tend if the patient live long enough to be replaced by atrophy, so that at length the complete disorganization of the nerve may take place. The changes are essentially chronic in their course.
7. That though atrophy of the optic nerves may thus succeed to a slight chronic interstitial neuritis it is also not unfrequently primary *at the disc*; the atrophy may be complete, the patient becoming quite blind.
8. That the pathological basis underlying the appearances of slight neuritis may be broadly characterized as a tendency to overgrowth in the connective elements of the nerve; the trabeculæ not only getting greatly hypertrophied, but the neuroglia corpuscles also becoming very large and numerous; these parts thus grow at the expense of the nervous elements, which subsequently atrophy.
9. That in the cases of primary atrophy, the pathological appearances eventually reached, though somewhat similar, may possibly take place in the reverse order *at the disc*, the nerve fibres being the first to dwindle, and the fibrous elements, trabeculæ, etc., subsequently taking on increased growth.
10. That in a considerable proportion of the cases in which atrophy of the optic discs is met with, spinal symptoms are prominent in the disease, these symptoms pointing in the direction of posterior or lateral sclerosis of the cord; but that this connection is by no means invariable.

Among these cases, having an average age of 55 years, 13,7 per cent., presented opacities of the lens, slight or considerable, which is a much higher percentage than would be found in the population at large of the same average age, and furnishes an illustration of the general impairment of nutrition common in the insane.

A HAIRY VACCINATION.—M. P. Diday (*Lyon Medical*) describes the case of a healthy child of 11½ months, that was vaccinated with animal vaccine furnished by the municipality of Lyon. The matter was introduced by two punctures on the anterior surface of the middle third of each thigh. The local inflammation was quite considerable, but the vesicle developed regularly and ran its proper course. Sixty days later, however, a crown of hairs made its appearance about the cicatrix. From being delicate, downy and nearly colorless at first, they soon took on length, color and body. Four months later there was presented the curious spectacle of a still reddish cicatrix surrounded by a double and triple row of hairs of 6 to 8 millimeters in length, the color of which, like the hairs of a red cow, stood out in bold contrast against the absolutely smooth skin of the child. The plate which carried the matter, being carefully examined, was found to contain three or four very small hairs visible to the naked eye.

THE value of crushed ice as a dressing for burns and scalds first pointed out by Sir James Earle, is confirmed by Dr. Richardson. The ice, after being reduced by crushing or scraping to a fine state of division as dry as possible, is mixed with fresh lard into a paste, which is placed in a thin cambric bag and laid upon the burn. This is said to banish all pain until the mixture has so far melted that a fresh dressing is necessary.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 65 RANDOLPH STREET,
CHICAGO ILLINOIS

SATURDAY, JANUARY 3, 1885

EXPLANATION —The issue of the 26th number of volume three, dated December 27th, was delayed several days by the failure of a single galley of proof to be delivered at the proper time, through the post-office The list of names of Permanent Members published in compliance with the by-laws of the Association, every third year, also occupied two pages more than was expected, and consequently crowded out the few editorial paragraphs prepared for that number The title page and very full index to the volume, which are so placed in the middle of the number that they can be readily removed and placed in front of the volume by the binder, and the convenience, for reference, of the complete list of members of the American Medical Association, will make the number a very valuable one, notwithstanding the absence of all ordinary reading matter All but a very few of the papers presented in the several Sections of the Association during the recent meeting in Washington, have now been published in full in the JOURNAL, many of them accompanied by interesting discussions The publication of the few that are left, will be completed in the next three or four weeks, but the valuable papers from other sources already accumulating on our hands, and the more extensive arrangements for reports and correspondence from the chief medical centres, both in this country and in Europe, furnish ample guarantee that the pages of the JOURNAL will continue to be filled with matter of interest and importance to those engaged in every department of the profession As the present number commences another volume, this is a good time for new subscribers to send in their names and money for the year 1885

PULMONARY SYPHILIS —This is a manifestation of syphilis which it is safe to assume few general practitioners have ever recognized This is due both to the rarity of its occurrence in adults, and to the difficulty attending its positive diagnosis The occurrence of a syphilitic form of phthisis was recognized by Morgagni, while Portal, Morton, Graves and Stokes admitted the likelihood of such a condition, from their observation of the clinical fact that some cases of bronchial catarrh were greatly benefited by mercury It was, however, left to Virchow, Wagner, Lorain, Robin and other contemporaneous investigators to describe minutely the pathological changes due to pulmonary syphilis Their researches were made chiefly upon the lungs of still-born syphilitic infants The latest contribution to this subject is by Dr A Hiller, in the Charite Annalen, Berlin, 1884, volume 9, page 184, and recapitulated in *Centralbl. f d Med Wiss*, October 4, 1884, page 702, as follows The anatomical appearances of pulmonary syphilis described by most pathologists are an increase of the interlobular and interalveolar connective tissue, resulting in induration of the part, with, in rare instances, retractions and wrinklings of the surface, the lobulated lung (*gelappte lunge*) of the Germans In addition, gummata are found, either isolated or in groups from the size of a hempseed to that of a goose's egg Hiller doubts the occurrence, as stated by some, of a syphilitic infiltration of an entire lobe, similar to that of croupous pneumonia. On the other hand, he coincides with Virchow, Webber, Lorain and Robin in recognizing a process known as "white hepatization," which is analogous to the catarrhal pneumonia of children, and may occur in adults as well as newly-born infants In this condition, it will be remembered, the terminal bronchioles and alveoli are distended with altered epithelial cells Wagner, on the contrary, holds that the alveolar walls thicken and gradually obliterate the alveolar spaces, without the epithelia taking part in the process In some instances this cellular infiltration is complicated by an œdematous saturation of the parenchyma, constituting what is known as a gelatinous infiltration The cavities not uncommonly found in syphilitic lungs Dr Hiller regards as bronchiectatic, herein differing widely from the view generally entertained, viz that they are the result of the breaking down and expectoration of gummata.

Some writers have described an acute form of phthisis syphilitica which manifests itself by a rapid disintegration of the pulmonary tissue, like that of tuberculosis Dr Hiller, however, after a critical perusal of the literature of the subject, draws the conclusion that, in the cases hitherto reported as instances of rapid syphilitic consumption, adequate proof is wanting of there having been a real ulcerative destruction of the lung structures, the same as takes place in pulmonary tuberculosis, and hence that a rapid consumption of the lungs from syphilis does not exist He regards the cases in which the diagnosis was confirmed by an autopsy as nothing more than a combination of constitutional syphilis with true tuberculosis, and thinks that where cavities were found they were bronchiectatic Dr Hiller has collected and tabulated all of the published cases, 87 in number, in which a post-mortem examination is recorded Of these, 29 are regarded by him as having been either genuine tuberculosis or a combination of it with syphilis or cancer The remaining 58 were undoubtedly examples of syphilitic phthisis In typical cases the most constant pathological changes consisted of that increase of the interlobular and interalveolar connective tissue already mentioned, or of fibrous induration of that portion alone of the pulmonary structure immediately surrounding the bronchial tubes Next in the order of their frequency were found diffuse lobular consolidation, gummata, and circumscribed patches of peribronchial thickening, called by the Germans " nodular bronchopneumonia " In non-typical cases, there had existed a pneumonia either of traumatic origin, as set up by foreign bodies in the air passages, or a croupous pneumonia which had been modified by the preexisting syphilis

The author then details two cases occurring in his own practice of genuine syphilitic phthisis, in which he was able to watch the progress of the disease to the end, and to obtain post-mortem examinations Although there were the usual symptoms of a pulmonary complaint—emaciation, cough, dyspnœa, etc , the course of the disease did not correspond with that of tubercular consumption The anatomical characters were likewise found to differ from those of tuberculosis, agreeing fully with those of syphilitic phthisis already described

The diagnosis of pulmonary syphilis can never be determined, *intra vitam*, with absolute certainty, but only conjectured if there exist at the same time the characteristic lesions of constitutional syphilis To this end laryngoscopical and rhinoscopical examinations should never be omitted In differentiating between a given case of suspected phthisis syphilitica and tuberculosis, the detection of tubercular bacilli in the *sputum* would, in Dr Hiller's opinion, decide the question

Lancereaux considered a case of phthisis as syphilitic if, in addition to the presence of characteristic lesions of the mucous membranes, the pulmonary affection was unilateral, with signs of consolidation, and it might be of excavation But Wilson Fox justly remarks that a syphilitic disease of the lungs may be bilateral

Syphilitic phthisis possesses great therapeutical interest Some clinicians have seen marked benefit result from the administration of mercury and iodide of potassium, while others have noted no improvement

In a case of this affection which we had the privilege of observing in von Ziemssen's clinic at Munich, the process was situated in the middle lobe of the right lung, and Ziemssen then remarked that according to his experience this was the most frequent site Probably no weight is to be attached to this statement

MISSING NUMBERS OF THE JOURNAL —As the preceding number completed volume three of the JOURNAL of the Association, it is a good time for every member and subscriber to look carefully over his file, and see if it is complete and all the numbers in good order If not, send us a postal card at once, stating the *numbers* missing or injured, and we will supply them without delay It is much more convenient for us to do this now, before the extra numbers of the volume are tied up and put out of the way, and there is much greater certainty that numbers wanted are at our command than will be the case six or twelve months hence

FEWER MEDICAL STUDENTS IN THE MEDICAL COLLEGES —It is stated in some of our exchanges that there are not as many medical students, in the aggregate, attending the medical colleges throughout the country during the present winter as during the past two or three years This is probably largely due to the extreme stringency in the monetary and business affairs of the country

OHIO STATE SANITARY ASSOCIATION —The Second Annual Meeting of this organization will be held at Columbus, Ohio, on February 5 and 6, 1885 Full programme for the meeting will be issued in due time by the Secretary, R Harvey Reed, M D , of Mansfield, Ohio

PROF DARLING, for many years well known as an eminent teacher of Anatomy in the Medical Department of the University of New York, died on the 25th inst

DR EDWARD JARVIS, one of the most philanthropic and deservedly eminent members of the profession in Massachusetts, recently died in Boston at the advanced age of 81 years

SOCIETY PROCEEDINGS

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated meeting Thursday, Dec 4, 1884 The President, R A Cleemann, M D , in the chair

Ovarian Tumor —Dr Drysdale presented a polycystic ovarian tumor which he had removed that morning He had first seen the patient with Dr C R Prall, May 5, 1884 She was a married lady, 59 years of age, pale, thin and delicate looking She had had eight children, the youngest of whom was then sixteen years old With some trifling exceptions her menstruation had been perfectly natural until two months before, since then she had had a constant and sometimes profuse discharge of blood from the vagina, which still continued She first discovered the tumor in March, 1884

On examination Dr Drysdale found a semi-solid, smooth walled, globular tumor, occupying the lower part of the abdomen and reaching nearly to the umbilicus It was freely movable, did not fluctuate, but was elastic and a little tender to pressure Vaginal examination revealed a lacerated cervix The sound entered the uterus two and a half inches, taking a direction to the right of the tumor On deep pressure the end of the sound could be felt at the lower part of the right border of the mass While the sound was in the uterus the tumor could be moved freely without affecting it Dr Drysdale diagnosticated a multilocular ovarian tumor

By the 5th of June, one month later, it reached nearly to the ensiform cartilage From this time it increased rapidly in size, and when it was removed filled the abdomen, pressing the lower ribs outwards It proved to be a multilocular tumor of the left ovary

His object in bringing it before the Society was to obtain an opinion from the members as to the cause of a phenomenon which was observed in the early stage of the growth When the patient first noticed the enlargement, she found that when she would lie on her right side, the tumor, as if lighter than the surrounding parts, would ascend to the left, and when on her left side, would rise to the right She informed Dr Prall of this and he naturally supposed she was mistaken, but a careful examination of the tumor while she changed her position verified her assertion As the mass increased in size, this peculiar change of position ceased, and when the abdomen was opened nothing could be found to account for the singular behavior of the growth

Dr Parvin inquired about the length of the pedicle and the weight of the tumor

Dr Da Costa has a case under observation in which the condition of great mobility is present

Dr Drysdale replied that the pedicle was extremely short The tumor weighed thirty-five pounds and was multilocular in character At the time of its removal he could not determine any fluctuation Every parovarian cyst is movable in its early stages, He intended to call attention to the peculiar and, to him, unaccountable motion of this particular cyst

Dr Chas Meigs Wilson presented the histories of three cases in which the hydrochlorate of cocaine had been used with the hope of obtaining local analgesia, and reported negative results

Malignant Disease of Ovaries, Cystic —Dr D Longaker exhibited the specimens with the following history The subject from whom this specimen was removed was a German woman, 63 years old She had been married the last 27 years of her life, and was sterile During the last five months she was under the care of Dr Jos S Gibb, of this city, at whose request I first saw her and by whose kindness I am enabled to report the case The menopause was established at fifty-three, ten years ago The patient had always enjoyed fair health, but four years ago she again began to have a bloody discharge from the vagina For this she consulted a doctor and was soon well again The date of the onset of her last illness was indefinite It was insidious, and the particular symptom for which she desired relief was inability to micturate, this was found to be due to suppression of the secretion of urine, as the bladder was empty There was also decided interference with nutrition Her appetite and strength failed rapidly The urine was found to contain a very small amount of albumin She had occasional nausea and bilious vomiting and diarrhœa She suffered with pain in the left side of the abdomen On examination the doctor discovered a hard tumor, nodulated, to the left of the uterus, projecting upwards into the left inguinal region, it was adherent and but slightly movable She was first seen by me on Oct 6 At this time she was in bed, suffered from orthopnœa and was unable to rest or lie down Her abdominal cavity was greatly distended by a fluid which had accumulated rapidly in the previous three or four weeks Œdema of the ankles had been noticed a few days before Her general appearance was decidedly anæmic and cachectic The abdomen was very tender to palpation, especially over the left inguinal and hypogastric regions The flanks were bulging and were flat on percussion The tumor could be indistinctly outlined, immobile, lying in contact with the left ilium, dipping down into the true pelvis behind and to the left of the uterus and distinct from it The cervix had undergone senile absorption, but from the os externum a small polyp was found hanging in the vagina Oct 7 she was tapped, a large bucketful of a brownish-red fluid, of specific gravity 1020, was removed On microscopic examination it was found to contain blood and various corpuscles and epithelium (The ovarian cell was not found) It contained paralbumin

A more careful examination now revealed a circumscribed, clearly defined, firm, nodulated growth in the region already indicated It was found adherent, and conld be only slightly displaced It was of the size of a large fist Palliative treatment was continued, but the patient's condition gradually grew worse There was again a slight accumulation of fluid in the abdominal cavity She was subject to attacks of bilious vomiting and diarrhœa alternated with constipation There was no apparent increase in the size of the tumor, and during this period pain was not a marked symptom At no time was there acute suffering She died of exhaustion, November 27

Autopsy on the next day by Dr Gibb, in the presence of and assisted by Dr E W Holmes and myself The subcutaneous fat had been almost entirely absorbed The parietal peritonæum was covered with lymph, with numerous nodular elevations in various stages of organization The intestines had contracted numerous adhesions The capsule of the liver was one eighth inch thick In the mesentery there were also deposits of lymph, some of which were more recent and less organized The abdominal cavity contained about two quarts of fluid, the same as that already described

On the left side, extending two inches above the pelvic brim, was found a tumor apparently solid, but which, on close examination, was found to be cystic One of the largest of the cysts had ruptured—the opening was found at the posterior-inferior portion of the growth It was not recent The capacity of the emptied cyst was about four ounces The tumor dipped down into the true pelvis between the broad and utero sacral ligaments of the left side It was adherent, and was removed with great difficulty On incising and freely opening the cyst some coagulated fibrin was found, the remains of a hæmorrhage into the cavity When it was entirely removed it was found to arise from the left ovary The oviduct was slightly dilated, and its fimbriated extremity was adherent to and spread out over the tumor

On the right side, in the broad ligament, there is a cyst slightly larger than the tumor Its contents are dark and very dense It is very heavy The cyst is surrounded by a dilated Fallopian tube containing a clear, transparent fluid of a bluish-white hue At its widest part it is an inch in diameter Behind and below this cyst is found the right ovary It is adherent, flattened out and seems continuous with it The entire specimen was carefully dissected out as it is shown From its rapidly fatal tendency, with the macroscopic appearance of the tumor, there is very little doubt that a microscopic examination will reveal it to be malignant Though, perhaps, possessing the greater pathological interest, there are also a few points in the case which may concern us in regard to diagnosis and treatment Study of the fluid at first caused a suspicion that it came from a cyst Its high specific gravity and the chemical tests to which it answered favored such a view But this was entirely at variance with the history of rapid accumulation and absence of physical signs indicating the existence of a large cyst It was apparent at the autopsy that an attempt at extirpation could only have hastened the fatal result The specimen was referred to a committee for further investigation

THE Cincinnati branch of the Western Society for the Suppression of Vice last year seized and destroyed over nine hundred pounds of obscene books and 165,900 pamphlets, circulars and cards, 1,100 photographs and 137 negatives

STATE MEDICINE

REPORT OF LAWS REGULATING THE PRACTICE OF MEDICINE IN THE UNITED STATES AND CANADA.

BY RICHARD J DUNGLISON, A M , M D , OF PHILADELPHIA, PA , AND HENRY O MARCY, A M , M D , OF BOSTON, MASS

Read before the American Academy of Medicine, at its Annual Meeting at Baltimore, Md , Oct 29 1884 approved for publication by the Council

Since the Annual Report of your committee was presented to the Academy, at its meeting in New York, in October, 1883, but little change has been effected in the legislation already operative in many of the States, or in the introduction of new laws regulating the practice of medicine in States or Territories in which the public were not already legally protected Virginia is the only State in which a Legislature has, during the year past, contributed anything of general or special interest to the sanitarian or humanitarian in the restriction of unqualified practitioners

In some of the States and Territories the Legislatures meet biennially, and have not, therefore, had the opportunity offered them of passing such measures as are urgently demanded in the interest of the public health Whether they would accomplish anything remarkable in this direction, even if the most abundant opportunities were available, it would be impossible for any one, familiar or unfamiliar with the general uncertainty and crookedness of methods of legislation, to conjecture

Under these circumstances, there being so little for your committee to report in regard to additional legislation restrictive of medical practice, it has seemed to them that it would be appropriate to take a brief glance at the present condition of the laws bearing upon the subject, and to secure an expression of the views of those actively interested in the various sections of the country in their efficient working With this object an extended correspondence has been entered into with Governors and Secretaries of States and Territories, with Secretaries of State Boards of Health and of State Medical Societies, and with other gentlemen interested in measures of public sanitation, and the replies elicited offer an excellent medium for an intelligent appreciation of the condition of State legislation, at the present moment, on this important subject

Dr J L Cabell, of the University of Virginia, President of the National Board of Health, who kindly furnishes a copy of the new law, makes reference to the fact that in Virginia—

> "Prior to the passage of this Act any person who chose to call himself a physician, and was assessed with a license tax as such, had any privilege that was accorded to regularly graduated physicians The new Act has some defects, which it is hoped may be corrected by future legislation, but has one great merit, in requiring *all* candidates for practice, *whether graduates or not*, to undergo an examination by the Board of Medical Examiners, to be appointed by the Governor, on the nomination of the State Medical Society"

Dr James E Reeves, Secretary of the State Board of Health of West Virginia, asserts that—

"No statute passed by a Legislature was ever more heartily welcomed by the whole people than has been the law regulating the Practice of Medicine and Surgery in West Virginia Its operation from the date of its passage, March 8, 1881, to the present, has been a continued success—a blessing to every citizen of the State, and a strong arm to uphold the dignity of the medical profession within our borders No changes in the law are contemplated by our Board We are satisfied to 'let well enough alone'"

Dr L Julian Picot, Secretary of the State Medical Society of North Carolina, mentions, as a feature of the law in force in that State, that under its provisions—

"Practitioners are not allowed to collect bills by legal process unless licensed by the State Board of Medical Examiners The Board is elected every six years by the State Medical Society The present law is not satisfactory to the better class of the profession, nor will it be until it is made a misdemeanor to practice without a license An effort will be made to secure the passage of an Act to this effect If successful, then the profession of this State will be happy"

Dr A S von Mansfelde, Permanent Secretary of the Nebraska State Medical Society, writes as follows

"The law, as it now exists, is inoperative, because any infringement upon it becomes a criminal offence, the common law providing that, in such cases, the defendant shall be faced by the witnesses of the prosecution To procure witnesses from distances, the places where bogus diplomas are manufactured, as, for an example, Philadelphia, Cincinnati and St Louis would involve a cost to which neither individuals nor societies are equal, therefore, the failure of a law otherwise good enough I shall surely introduce the Illinois law at the coming session of our Legislature, January, 1885, and have some hope of its passage"

Dr C C Fite, Secretary of the Medical Society of the State of Tennessee, states that

"There are no laws of any kind on medical practice in Tennessee, and not likely to be soon, as the profession in this State is divided on the question We have received a considerable addition to our ranks recently, by the enforcement of laws in other states forcing the 'ne'er do wells' to seek more hospitable climes, and Tennessee welcomes them all"

In commenting upon the working of the law regulating the practice of medicine in the State of Louisiana, Dr Lucien F Salomon, of New Orleans, writes thus intelligently and fully

"The act now in force has several defects, which it would be well to point out

"In the first place, section 3 allows the privilege of registration to persons who have been practicing in the State for more than *five* years prior to the passage of the act, regardless of qualification, and the result has been that every charlatan, quack, and unqualified person who pretends to practice medicine, or styles himself 'doctor,' has hastened to take advantage of and profit by this privilege, while many regular physicians, possessing diplomas from reputable colleges, have either refused or neglected to register, the neglect or refusal being, in a great measure, due to this provision which places upon an equal footing with them irregulars, 'herb doctors,' quacks and impostors Out of a total of 1,027 physicians in the State of Louisiana, 758 have registered, of whom 141 are without diplomas, and have been *legally* registered, after having made affidavit of five years' practice In the City of New Orleans there are about 270 persons practicing or claiming to practice medicine Of these, 237 have registered, 25 of whom are without diplomas Of course, the defect existing in section 3 will, in time, correct itself The legislature evidently did not intend to make the law retroactive, inasmuch as by so doing it was said that some who had been practicing without diplomas for many years might be deprived of their livelihood, but the evil has been saddled upon the people of the State by this saving clause, and there is no present remedy

"Another grave and striking defect is found in section 6 This section provides that action shall be brought for violation of this act in the name and for the benefit of the Charity Hospital at New Orleans But the Board of Administrators of the Charity *Hospital* have never attempted to prosecute, probably because, it may be, that they do not consider it within their province to do so, and probably because registration is demanded at the office of the State Board of Health, and until very recently no effort has been made on the part of the Board of Health to inform the proper officials of the Hospital of the names of persons practicing in violation of the law, and unless so done there is no way of reaching delinquents Besides, the Charity Hospital (or any one else, for that matter) does not appear to be very desirous of prosecuting, for the law, while providing a penalty, prescribes no method of enforcement The last line of Sec 6 reads, 'he shall be subject to criminal prosecution, and be punished in the manner prescribed by law for violations of this act' Now this would answer very well, and make the law effective were any such prosecution provided for, but, unfortunately, nowhere upon the statutes of Louisiana can any such provision be found, and, as a consequence, the law is to this extent inoperative This is an oversight which the profession of the State, through the State Medical Society, has endeavored to have corrected, but at its last session the Legislature neglected or refused to make any amendments to the existing law or take any action whatever in regard to State Medicine With a view to making the present law as effective as possible, and to endeavor to obtain a complete registration of physicians in the city of New Orleans, at least, I, as a member of the Committee on Registration of the Board of Health, a short time since introduced a resolution, which was unanimously adopted, providing for the enforcement of the act as far as could be done under existing circumstances Said resolution *provided that, under the provision of Sec 6 of the act,* the Board of Health would refuse to accept certificates of any nature whatsoever, or recognize the same as legal, when issued by any physician who had failed to register, or by any person whose name did not appear upon the books as having duly registered, in compliance with the law (The Board of Health is by law constituted the registrar of births, marriages and deaths, for the city of New Orleans) The result has been that since the adoption of this action by the Board 41 have registered, bringing the total number registered in New Orleans to the figure stated above, 237

"At the same time the Secretary of the Board of Health was instructed to forward to the Administrators of the Charity Hospital the names of those persons practicing without having registered, with the request that the attorney of the Hospital be instructed to prosecute by civil action, and attempt to recover the prescribed fine for the benefit of the Hospital But nothing has as yet been done to this end, nor has any reply to the request been received by *the Board of Health* Were the power given to this Board to prosecute, I think that violations of the act would be less numerous, for the amount to be recovered in fines, and the desire to protect the public from unqualified and ignorant practitioners, would be an incentive for active measures Still, taken all in all, the law as it now exists is a vast improvement upon our former condition, when there was nothing to deter peripatetic quacks and pretenders from gulling and fleecing a credulous public"

From Dr G D Hersey, Secretary of the Rhode Island Medical Society, we learn that

"Through the efforts of the Society one much needed reform has been secured, by which the old coroner system has been abolished, and, instead there has been instituted a system of Medical Examiners The law went into effect July 1, 1884, and gives satisfaction"

Dr E P Fraser, Secretary of the State Medical Society of Oregon, expresses the regret that they have no medical legislation whatever, as yet They have a bill ready to present at the next session of the Legislature, and hope to secure its passage

The prospects for successful medical legislation in

Massachusetts seem much more encouraging, now that the State Medical Society has interested itself actively in the matter, by entrusting it to the hands of a large and influential committee of that body The effort to induce legislative action last winter failed, as it had previously done, but it is believed that the profession will now enter more earnestly into the prosecution of the work, with better prospects of success

Dr Walter Coles, of St Louis, Missouri, writes as follows —

> "The law now in force is not all that might be desired, but was the best that could be secured by way of a start It has served a good purpose in interesting the more progressive element of the profession in the importance of legal restrictions, etc, and will, undoubtedly, prove an efficient entering wedge to something better and more efficient, in the near future"

Dr William Elmer, Jr, of Trenton, Corresponding Secretary of the State Medical Society of New Jersey, states that—

> "The law works fairly well in this State, although there is no authorized power to prosecute offenders unless by individually assuming the trouble and unpleasantness therefrom resulting"

Dr P H Millard, Secretary of the State Board of Medical Examiners of Minnesota, states that—

> "In Minnesota the Supreme Court has very recently affirmed the constitutionality of the Act in all its features This decision is important, as the Act is similar to those of Illinois, West Virginia and Missouri, and may influence and confirm the action of those States in the case of delinquents or of those answerable to the law The law in Minnesota is said to be giving very general satisfaction"

Dr J P Booth, Secretary of the Medical Society of New Mexico, speaking of the law which was passed in March, 1882, regards it as a good one, so far as it goes, but it does not go far enough

> "By it, those desiring to practice are required to present their diplomas for examination to the Board, or if they have no diplomas, to appear in person before the Board and undergo a satisfactory examination in Anatomy, Chemistry, Physiology, Surgery, Materia Medica and Therapeutics and Obstetrics The Practice of Medicine is not included *The Board consists of three regulars*, two homœopaths and two eclectics The law paradoxically prescribes that this body, in its rulings and actions, shall be governed by the Code of Ethics of the American Medical Association It is the aim of the Southern New Mexico Medical Association, of which I have the honor to be Secretary, to amend the law whenever it is possible to do so Two years must elapse, however, before much can be done, as the present Legislature at its last session passed a law to retain their seats until 1886"

Dr J A Dibrell, Jr, Secretary of the State Board of Health of Arkansas, does not speak in any terms of enthusiasm of the condition of medical legislation in that State He states that—

> "The present Act is by no means satisfactory The medical profession of Arkansas, for a number of years, made efforts to secure the passage of a bill to regulate the practice of medicine Such efforts were always defeated by the influence brought to bear by quacks upon the members of the Legislature The bill, or act, now in force was passed in 1881, and it was thought it would be better than none at all, and that is about all that can be said in its favor"

Dr M W Russell, Secretary of the New Hampshire State Medical Society, writes that the law of that State works very well, with but little friction, and gives general satisfaction

Dr Charles D Smith, Secretary of the Maine Medical Association, states that efforts will doubtless be made by a committee of the State Medical Society to secure a law establishing a State Board of Health and Registration, at its next session

Dr J S Richmond, Secretary of the Vermont State Medical Society, writes as follows —

> "In 1876 a law was passed requiring practitioners of medicine to obtain a license of a Board of three Censors appointed by our State Society, or of a Board of Censors appointed by Chartered County Societies In 1878 some *tinkering* was added In 1880 our Society, not liking the law, did not appoint censors, intending to treat the law as a dead letter Last June *the law was brought before our semi annual meeting* We found that the old Board of Censors, by the law, held their office until others were chosen I have supplied the Board with blanks, and the profession very generally have a license We anticipate that a State Board of Health, measures to enable us to control diseases, etc, will come before our Legislature, which meets Oct 1, 1884"

Dr W G Brownson, of New Canaan, Connecticut, writes that since our last annual report to the Academy—

> "An attempt was made, with the view of suppressing irregular traveling and advertising quacks, but it was defeated in the Legislature A bill making it a duty to label all patent and proprietary medicines, was also defeated"

Dr George W Cox, Secretary of the State Board of Medical Examiners of Colorado, expresses the belief that—

> "The State Board of Health will endeavor to have more stringent laws passed at the next meeting of the Legislature"

Dr W J Burt, Secretary of the Texas State Medical Association, writes to say that—

> "The present law is not satisfactory, and the State Medical Association has drafted a bill which will be presented to the next Legislature, in January, 1885"

Dr Hector Galloway, Secretary of the Dakota Medical Society, states that—

> "An effort was made by our local society (Cass County Medical) to obtain from the last Legislature an Act similar to that of Pennsylvania, requiring registration, etc, but the consideration of it was not reached before the Legislature adjourned An effort will probably be made next winter to have the matter taken up and considered"

Dr J T Reeve, Secretary of the Wisconsin State Board of Health, writes as follows —

> "No change has been made in the laws which regulate the practice of medicine in this State since the date of the last meeting, except that a section of a new law requires medical men to report contagious diseases occurring in their practice I am not aware of any movement looking to a change in the laws regulating the practice There is, however, a growing interest in this subject, and an increasing belief that there ought to be greater restrictions upon the practice of medicine"

Dr William Marshall, of Milford, Delaware, states that—

> "The law of Delaware, now on the statute book, regulating the practice of medicine, is generally regarded"

The same remark may be made in regard to the law of California

On the other hand, Dr James A Gray, of Atlanta, writes to say that—

> "The law in force in Georgia is very unsatisfactory to a large number of the best physicians, and yet there seems to be little hope that anything better will be enacted in the near future"

Dr E S Elder, Secretary of the Indiana State Board of Health, thinks it probable that—

> "An effort will be made to pass a medical law at the next ses-

DOMESTIC CORRESPONDENCE.

DETROIT, MICH., December 15, 1884.

TO THE EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

The JOURNAL of the 29th ult. contained a report of a case of "Unilocular Ovarian Cyst weighing ninety-five pounds, successfully removed by Dr. George E. Ranney, of Lansing, Michigan." In this report Dr. Ranney claims to have performed the operation, and generously gives Dr. Post, of Lansing, and myself, credit for valuable assistance which we rendered him. Inasmuch as the *Medical Age*, of this city, in its issue of October 25, contained a notice of this same case in which I was credited with having performed the operation, assisted by Dr. Ranney and others, the discrepancy has called forth sufficient comment to warrant, if not, indeed, to demand a statement from me. This statement I am constrained to make rather in the interest of truth and honesty than from a desire to enter into an unseemly controversy.

I was waited on by Dr. Ranney on the 6th of October last, and received from him a description of the case referred to, and a statement of his relations to it. He had assumed charge of it, and had advised an operation, which he had engaged himself to undertake. It was one the importance of which he fully realized, and the realization convinced him of the advisability of having present at the operation some operator of experience. In doing me the honor to request me to act in this capacity, it was expressly understood that, inasmuch as he had undertaken to perform the operation, he was to be permitted to identify himself therewith with sufficient prominence to satisfy the friends of the woman "that he was not a dead-head in the enterprise." The doctor's exact words, as I distinctly recall them, were: "I wish you to let me do as much as possible, for the family expect me to operate." On the strength of this request I considered myself engaged to operate. Had I thought of the possibility of his utilizing the case as the head of a list of possible future ovariotomies, I should certainly have declined any connection with it. I had known the doctor for about twenty years, and had learned to regard him highly as a citizen and as a general practitioner, but his fame as an ovariotomist had not been sufficiently established to warrant me in acting under his instructions in a case of the importance of that regarding which he consulted me, promised to be.

Pursuant to our engagement, I met Dr. Ranney at Grand Ledge on Oct. 8, and subsequently learned that the fact of my intended presence had been carefully kept from the knowledge of both the family of the woman and the local profession. But in view of our previous understanding I did not think this as strange as it might have seemed under ordinary circumstances. According to agreement, I had, furthermore, taken with me from my own office every instrument to be employed in the operation, even the sponges and the silk, which latter I had myself properly antisepsized by boiling, and not by means of carbolic acid, as one would infer from Dr. Ranney's statement it had been treated. Assistants, I submit, are not usually expected to furnish all the essentials to an operation. In addition to such antiseptic precautions as I took, the room, as stated by Dr. Ranney, was treated to a vigorous application of carbolized spray, produced, by the way, by my large Weir's Atomizer, which the doctor took with him from my office on the date of his call on me. I saw the patient for the first time when she was placed upon the table. Having made the necessary examination to confirm Dr. Ranney's diagnosis, she was etherized and I proceeded to make the abdominal incision. I then passed a sound over the tumor to determine the adhesions. I next introduced the trocar into the cyst, the walls of which were, however, so friable and the contents of which were so jelly like as to prevent the evacuation by this means. The tumor, by the way, was multilocular instead of unilocular or monocystic, as, of course, any ovariotomist of experience would expect it to be from its size and after having discovered the peculiar consistency of its contents. Owing to the character of the tumor, the cyst was broken up and its contents were evacuated by the hands. On attempting the removal of the tumor the abdominal opening was found to be rather small, and under my direction Dr. Ranney enlarged it. After the tumor had been sufficiently reduced to permit its extraction, I applied Storer's clamp shield at the junction of the pedicle and the cyst. After this I passed a dull perineal needle, armed with the ligature, through the pedicle and secured the ligature with a Peaslee's chain knot. After severing the stump I cauterized the end thereof with my Paquelin's thermo cautery which was heated by Dr. Post. This thermo cautery is what Dr. Ranney in his report calls "a hot iron." After cauterization, the vessels of the stump (three in number) were felt to be pulsating so energetically beneath the ligature of the pedicle, as to lead me to believe it would be best to "make assurance doubly sure." I therefore seized the exposed ends and requested Dr. Ranney to ligate them. I would especially note the fact, that the cautery was applied before the arteries of the pedicle were ligated, not after, as one would infer from the doctor's report. The contents having escaped through the broken walls of the cyst, into the cavity of the abdomen, it was found necessary to scoop them out with the hand and afterwards to employ the sponge, as the safety of the woman was very closely dependent on the success thus achieved. Dr. Ranney rendered me valuable assistance in this step of the operation and I desire to acknowledge my indebtedness for his dexterous manipulation of the sponge. This cleansing of the abdominal cavity consumed over two hours in its completion. After the above steps had been completed, I closed the wound by means of silver wire, first placing a flat sponge (as is my custom) over the intestines to catch the blood from the needle wounds. After applying the necessary dressing to the wound, I turned the case over to Dr. Ranney, and, doubtless, its successful outcome is due to the intelligent manner in which that gentleman carried out my instructions, given at the time and supplemented by advice by mail

The above is a faithful report of my and Dr Ranney's connection with the case, and with it before them, I am quite willing to leave it to the readers of the JOURNAL to decide who performed the operation

NATIONAL BOARD OF HEALTH.

CHICAGO, ILL , Dec 22, 1884

To the Editor —Having noticed in last week's issue of the JOURNAL, the bill presented to the Committee on Public Health on the above subject, and which doubtless will be introduced in Congress by Mr Beach, chairman of this committee, the thought has occurred to me, as doubtless it has to many others who have read the bill, that while it covers the ground very completely indeed for the purpose for which it is intended, a suggestion may not be devoid of interest at this time, to be offered, perhaps, as an amendment to this bill, or to that portion of it which relates *more particularly to the selection of members* which shall constitute the National Board of Health And I trust while doing so I may not be regarded as acting in the capacity of instructor to the honorable representative from New York, nor to those who assisted in framing this bill, but that I shall be accorded space in stating what I believe to be the sentiment of more than 90 per cent of the physicians throughout the United States, as well as the views of all the people The following is the bill as it now reads

" Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled That an act entitled An act to prevent the introduction of contagious and infectious diseases into the United States, and to establish a National Board of Health, approved March 3, 1879, be so amended as to provide that there shall be established a National Board of Health to consist of *one member from each State Board of Health now established, or which may be hereafter established,* etc , etc "

Assuming that the above bill, or a similar, one will be passed by Congress this winter, and the appropriation asked for granted, or that a suitable amount will be appropriated for the object of perpetuating a National Health Authority, does not the bill as it now stands savor just a little of partiality in the selection of members who shall constitute this National Board ? "

To illustrate We will suppose that Illinois has 5,000 well educated, honorable physicians, all of whom are engaged in the practice of medicine and surgery, of whom 1,500 are residents of Chicago and Cook county Are these 5,000 doctors to be ignored in the selection or the appointment of one of its members to the National Board of Health ? Are there no hygienists or sanitarians in this large number, from which a proper and judicious selection of one member for the National Board can be made, instead of confining the selection to one of the seven now constituting the Illinois State Board of Health ?

Are the Territories also to be slighted in this selection ? Of the several Territories, is it not to these newer countries that emigration is attracted and largely destined, and where disease is often generated ? Are there not hundreds of scientific medical men, eminent in the profession, living within territorial boundaries, that should have recognition, and also be eligible to membership in this National Board ? In making the above suggestions, far be it from my thought to decry or undervalue the different State Boards of Health, or any of the members thereof On the contrary, in the State of Illinois a number of its present members, and those who previously belonged to it, have already achieved national renown as sanitarians, as doubtless those of the other State Boards of Health have If I have succeeded in the above remarks in making my subject clear, and the interrogatories herein propounded merit the approval of those who may read them, and if the bill as already stated appears as an unjust one to at least 80,000 practitioners in the United States, for the reasons above stated, then, indeed, it is the duty of those whose attention has been directed to the subject, to promptly notify their respective representatives at Washington of the views herein set forth, or such portions thereof as merit their approval

Other thoughts occur to the writer, pertaining to the National Board of Health, or the establishment of a Health Bureau as a branch of our Government, which I shall not dwell upon at present, as this letter has been already extended to greater length than was originally intended

Very respectfully yours,
LISTON H MONTGOMERY

MURIATE OF COCAINE IN URETHRAL SURGERY.

The wide range of usefulness as an anæsthetic for cocaine seems as yet unlimited

After the many eulogies upon it in its effects to prevent pain in operations upon the eye, ear, nose, teeth, skin, I have one to add—that of its power to completely anæsthetize the mucous membrane of the urethra, permitting the painless introduction of the sound, and of enabling the surgeon to operate by cutting on *strictures* of the urethra by a completely painless method

My first case was a well built and healthy-looking man, 34 years old, unmarried Had gonorrhœa six years previous, treated himself with arg nit injections He stated the cure was complete He came to me on Dec 5, with an acute gonorrhœa Treated him by hot water injections medicated with zinc and hydrastin muriate Found that only a No 6 soft rubber catheter could be passed on account of strictures Continued the treatment until discharges ceased, which did so in a week I then concluded to operate on strictures by Otis's instrument I painted the urethral surface of penis for several minutes and repeated the operation at intervals of five minutes, obtaining at the end of twenty minutes complete anæsthesia of the entire urethral tract The introduction of a sound was painless, as likewise the cutting instrument The strictures were cut, *three* in number, without the slightest twinge of pain There was very little subsequent pain or soreness, and my patient was speedily cured

Case No 2 had suffered from stricture for four years, had a chronic gleet when he presented himself at my office I found stricture in membranous portion of urethra I introduced a soft rubber catheter down to the stricture and injected a four per cent solution of Merck's In ten minutes I forced the instrument past the stricture and incised in two places the fibrous band without pain Very little hæmorrhage, amounting to 4 or 5 drops in all, after which I passed a No 14 sound with little difficulty I feel safe in saying that this new therapeutic agent is still in its infancy of usefulness to the profession

ATLAS OF FEMALE PELVIC ANATOMY By D BERRY HART, M D, F R C P E, Lecturer School of Medicine, Edinburgh, etc, etc New York D Appleton & Co, 1884 From Jansen, McClurg & Co, Chicago

This is a new and important contribution to anatomical science The author is quite well and favorably known on both sides of the Atlantic, from his former works, "Manual of Gynæcology" (with Dr Barbour) and "Structural Anatomy of Female Pelvic Floor"

The present work is as masterly and complete as seems possible on such a subject Most of the delineations are new and valuable, especially those forming the plates on fœtal developments and the frozen sections

Imperfections in our knowledge of precise regional anatomy, especially in the diseases of women, have been the cause of confusion of ideas and disputed theories, with much fruitless discussion The present work will in future furnish a basis for greater accuracy and precision to all gynæcologists who will avail themselves of it

It is a handsome quarto volume containing about forty colored plates, all drawn from actual dissections with extreme care and fidelity As an instance of thoroughness seldom surpassed, the various frozen sections, with the bladder in all stages of fulness, may be cited The position and form of this organ when emptied and when distended, and the precise influence of its pressure upon other organs is thus shown with almost photographic accuracy This is true of all other points needing elucidation about the female pelvic viscera, *e g*, their positions in pregnancy, in parturition, in the virgin, in the fœtus, in the genu pectoral posture, etc, etc

Instructors cannot fail to find this splendid work a mine of usefulness in their classes

MEDICAL DIAGNOSIS A Manual of Clinical Methods By J GRAHAM BROWN, M D Second Edition Birmingham & Co, New York

This is an excellent treatise on physical diagnosis It is convenient in size It is written compactly, and is quite full and complete It is more than a treatise on physical diagnosis, although this constitutes the bulk of the volume, since it describes subjective as well as objective signs of disease The book is well worth reading Methods of urinalysis, both chemical and microscopic, are given in the discussion of symptoms and signs of disease connected with the urinary system

CLINICAL LECTURES ON DISEASES OF THE EYE Including the Conjunctiva, Cornea Sclerotic, Iris and Ciliary body By DR FRED RITTER VON ARLT, O O, Professor Augenheilkunde in Wien Translated by DR LYMAN WARE, Surgeon Illinois Charitable Ear Infirmary, Ophthalmic Surgeon Presbyterian Hospital and Protestant Orphan Asylum, Chicago Now in press

ORIGINAL ARTICLES

ON THE TREATMENT OF DIPHTHERIA

BY J W BROWN, M D , OF CENTRAL NEW YORK

Read in the Section on Diseases of Children of American Medical Association, May, 1884

Omitting the historical review of the nature and origin of this malady, together with its pathological, histological and disputed theories of formation, and practically ignoring symptoms, diagnosis and prognosis as beyond the scope of the present paper and time at my disposal, and assuming that we are all familiar with this affection and that our results have been disappointing when faced by an epidemic, by the unfavorable mortality averaging, as Oertel claims, 40 to 50 per cent the question naturally is suggested, Can we lower this fearful percentage? I present, gentlemen, a few facts gained from a study and experience of over one hundred and twenty (120) recorded cases occurring in my individual practice during a period of about fourteen (14) months Its plan is not new, being advocated by Tropean, and endorsed by Dr Whittaker, of Ohio, at the meeting of this Association in Richmond It promises, I think, more satisfactory results than common, and while recognizing the local nature, it does not advocate the radical caustic treatment of recent date and prominent endorsement During a practice of about ten years the usual sporadic cases were observed and with indifferent treatment the most of them recovered The present epidemic began in August, 1880, and continued with varying severity for about the time stated The causes are obscure, as we are situated in Central New York The surface of the country is rolling and well drained, the area of territory invaded may be estimated as about one half (½) mile by four (4) miles, averaging a descent of one hundred feet to the mile Geological formation is limestone and we have no stagnant water During a residence of nearly nine years no other epidemics were observed General sanitary condition the average of country villages Population about one thousand, manufacturing (mills) and farming the principal occupations Water supply mainly obtained from wells and springs, no sewerage, but the usual country "*back house*" The general type was severe, and no case has been recorded where distinct exudation was not present The catarrhal and croupous forms were readily recognized, many of the latter proving malignant The catarrhal form was readily merged into the croupous, and fauces were generally well covered in twenty-four hours

The invasion was generally sudden—chilliness being first complained of, which, with the pain in back and soreness of throat, soon told the story I regard it as *contagious*, having personally acquired it twice in less than six months from close attention to bad cases The temperature I could not rely upon, severe and even fatal cases having no extreme elevation from normal

The complications were numerous, and convalescence in many instances protracted My mortality was light, considering the severity of the epidemic The following are numbers of fatal cases as they occurred, with analysis of causes of death Nos 1, 6, 17, 19, 36, 66, 68—total, 7 In case I nasal hæmorrhage and asthenia can be assigned as the cause, and was unavoidable and almost assured, as she was not seen until about forty-eight hours before, and with neglect and lack of treatment fell an easy victim In case VI death was due to erosion of arteries in posterior nares, together with general debility This case had been progressing finely, but owing to my acquiring it, as I think, from him, and being confined to my bed, I did not see him Death ensued in about forty-eight hours, although his throat had been perfectly cleared at my last visit In case XVII death was undoubtedly due to the extreme severity An overwhelming attack, with complete systemic infection Membrane formed so rapidly and blocked throat so completely, that scissors had to be used to keep passages open and prevent suffocation Case XIX was convalescent Membrane had been entirely cleared, with no re-formation for forty-eight hours Death very suddenly from paralysis of the heart Case XXXVI was malignant, and died from complete systemic infection and prostration Sloughing of tonsils and nasal hæmorrhage Case LXVI, death was peculiar, and history not satisfactory, but I should judge from asthenia I saw him forty-eight hours previous, and throat was practically clean Had been severely affected, but was convalescent, appetite good, and I considered him out of danger Was prostrated with my second seizure, and I learned that a fatal result terminated the battle two days subsequently Case LXVIII, death in fifty-two hours Malignant, tonsils sloughed, nasal hæmorrhage Whole number of fatal cases, seven (7), from disease alone, three (3), from complications, four (4) There were but three cases in which treatment was without apparent effect, and who succumbed to the disease proper, and yet these measures were successful in relieving the fauces of the remainder, who perished from the complications.

The ages varied from an infant of 4 months to a lady of 60, but was mainly among those under 16 years. I regard it as a constitutional disease, with local affection of the throat as its most characteristic symptom, and consider the chief dangers due to systemic infection, with subsequent poisoning and prostration, and that to the *immediate* mitigation of throat symptoms by *topical* measures, together with urgent stimulation and constant support, must our chief reliance be made. I do not *dare* to sit down and let the throat take care of itself. No *half way* measures succeed. We *must be* thorough, and we must not palliate, or the "golden stair" will be ascended before we are aware, and our fancied security be an illusion. Two attacks with alarming severity is my excuse, so I may be allowed my objections to this delusion that we should cherish, "DON'T DO IT." And now, gentlemen, what shall we do? At my first visit I give 5 grains of calomel every four hours until bowels are thoroughly evacuated. This starts up secretions and eliminates much effete material, and in itself is of great utility. I have salt pork cut thin and rubbed full of table salt and bound over tonsils from ear to ear, fastening at the vertex (stitching through and through the muslin will prevent trouble some slipping). I touch the throat in ordinary cases once daily (although much depends upon activity of membranous formation), and in severe cases twice or more, though not too often, as increased irritation following too frequent applications in my own case was a painful illustration, and rendered me more careful afterward. Absorbent cotton held in a sponge-holder proves a happy medium for making applications, which consist of the following:

℞	Ferri pr. sulph.	ʒi	
	Glycerine and		
	Pure cider vinegar āā	℥ss	M.
S.	Apply.		

This when gently applied (not swabbed) and held for a few seconds in apposition to affected parts has the effect of penetrating the deposit, which shrivels and falls off, and also hardens the engorged tissues beneath. This in many cases does not occur at once, but may require repeated applications. Do not be tempted to make them too often, and above all, use no force in detaching that which is apparently loose, as I can personally condemn its bad effects. Septic absorption is less active from the coagulation and hardening of subjacent structures. Upon no account is force or swabbing to be resorted to, and unless suffocation is imminent or fear of swallowing membrane present, I would not forcibly detach it, as it forms all the more rapidly upon the torn and raw surface beneath, and systemic infection is all the more profound. Gently place cotton in apposition, and gentle pressure will be all that is required. I atomize throat freely, frequently and thoroughly, depending upon the severity of the case, with

℞	Ferri pr. sulph.	gr. x	
	Pure cider vinegar		
	Pure water āā	℥ss	M.
S.	With atomizer.		

In nasal diphtheria, if inhaled at time of atomization, benefit will be more pronounced. Any atomizer will be found convenient that throws a liberal spray, and in epidemics it is indispensable that each patient should procure his own, which must be scalded frequently. Atomizer must be well applied to affected parts and spray thrown well up in posterior nares for a few minutes, when practicable. Always *know* that it is thoroughly done or you will be disappointed in your results. Young children may require force, but the atomization must be made at short intervals, and have nurses fully understand the imperative necessity of complying. Among the worst cases of laryngeal variety I ever saw was a child of seven years, whose recovery is due to persistent and thorough atomization given by his father. Epiglottis was loaded for two days, but we persevered and eventually won the battle. Gargles of brandy and water, chlorate of potassa, salt, pepper and vinegar are useful but must in no way interfere with thorough and regular atomization. As exudate re forms more rapidly during night, greater caution and care are required. As constitutional remedies I give after bowels are freely evacuated

℞	Tr. ferri chlorid.	ʒss	
	Saturated solution potass. chlorate		
	Syrupi simplex āā	℥iv	M.
S.	ʒi every hour.		

Three grains each of potassa chlorate and quinia sulphas every five or six hours is generally beneficial. All should be cautioned against swallowing the membrane, as it produces symptoms resembling arsenical poisoning. When taken in quantities, potassa chlorate in solution in teaspoonful doses occasionally is of value as a neutralizing agent. Know that the nursing is of the best and not *too* frequent changes; *know* that your directions are obeyed as to the minutiæ or often your efforts are in vain. See personally that *enough* nourishment is taken, *nolens volens*. Milk is to be preferred as being more readily assimilated; beef tea, extract, etc., etc., may be used. I advocate stimulants from the first, even in mild cases. There seems to be an enervation of heart even from the first; a diminished "vis-a-tergo," and heroic stimulation may win the day as I personally know, even when convalescent; and I think my results were better and I had less alarming cases of enfeebled heart after my adoption of more thorough stimulation. Good bourbon or rye whiskey or brandy can be used, as may be preferred. The quantity must be regulated by the judgment of attendant and effect produced, the pulse being our guide. I gave over a pint of whiskey in less than eight hours to a boy of seven years, and no ill effects were perceptible as he recovered, thanks to the stimulation. Kidneys must act properly, also bowels at least once every second day.

Isolation *must be enforced*. Fumigate daily with sulphur upon live coals. Disinfect all discharges with cupri sulphas. Take plenty of fresh air, keep out draughts In my family of seven none contracted disease, although two were under three years of age Same results generally when orders were fully obeyed

A history of my own attacks may be of interest and for once I know all about it The first was extremely severe Membrane very thick and re-forming very actively Throat made worse by too frequent applications Prostration extreme, malignant tendency for twelve hours, greatly diminished heart's action and enfeeblement Tendency for heart clot on fifth day Convalescence rapid Loss of twenty pounds The second attack was due to exposure to Case 68 where I was compelled to plug nostrils Throat affected in twelve hours Blood oozed from fauces for twenty-four hours before exudate appeared, which was of the greenish malignant kind Right tonsil partially sloughed Recovery protracted, and I did not feel perfectly well for over a year afterwards Topical measures and *energetic* stimulation were strictly enforced

After convalescence is established, good food, tonics and fresh air are required

Tracheotomy was performed once, but I would not advise it again I have abandoned all treatment for the following, and base my deductions upon results obtained with no selection of cases Let our gospel be one of thoroughness, stimulation, topical applications, tonics and nourishment Look upon the localized deposit and relieve it, and your battle is more that half won Do not be deluded by this lime water treatment, and abandon the use of nitrate of silver Avoid harshness, but use whiskey

DISCUSSSION

Dr S W Smith, of New York, wished to know how the essayist made his diagnosis, as other diseases closely resemble diphtheria such as follicular pharyngitis, and can only be recognized by washing off the membrane

In the dispensary where he was assistant there were 175 cases seen monthly, or about 1,800 cases yearly Met during the two years 25 cases of diphtheria Catarrhal tonsillitis and follicular pharyngitis in many cases resemble diphtheria, but in those diseases the membrane can be removed without hæmorrhage The disease can find a point of departure from other parts of the body besides the tonsils Recalls a case where the first manifestation was on the genitals and passed into the vagina The child died

The statistics of the State of Vermont give a mortality of 50 per cent Dr Billington's (chief of the Dispensary service) treatment consisted in washing out mouth and nose with a solution of salt water and giving internally chlorate of potassium, tincture of the chloride of iron and glycerine

Quinine and alcohol were not given because there did not appear to him to be any indication for their use Lost a case where it was impossible to wash out throat Believes the disease to be constitutional and local in character

Dr A Behrend, Washington, D C , called attention to the fact that the cases here were uniformly fatal when hoarseness commenced

Dr Franklin, Ohio —Why does Dr Smith object to quinine?

Dr Smith —Because fever went down when the throat was well washed out Milk was given freely during the attack

Dr Franklin —Out West it is necessary to give quinine on account of malaria Has found iron and quinine of great benefit Also employs a gargle of salt and vinegar as was first recommended by Trousseau This brings the membrane up in large blocks Has had few deaths since he adopted this line of treatment In rheumatic throat trouble guaiacum has been found good Rheumatism complicates this very often

Dr J Lewis Smith, N Y , does not agree with those who hold that the disease is a local one Local treatment does not cure Must be constitutional because the kidneys are so early affected It is either constitutional at first or becomes so very quickly What must we use if it is a constitutional disease? Micrococci are found everywhere, kidneys, etc Have we any remedy for this disease? Alcohol appears to meet the indication and can be used in large quantities without intoxication This is much better than iron and quinine Has been led to look with distrust on the antiseptics No agent can act on the micrococci without hurting the system They would destoy the normal cells as quickly as the morbid matter The sulphite of soda, phenic acid, etc , do not accomplish as much as alcohol Jacobi and others look with favor on Pepper's treatment with the bichloride of mercury in small doses In syphilis this improves the blood corpuscles In this we may have an important agent Tenesmus may result This is a good agent according to New York physicians Looks with distrust on statistics The disease varies the same as the scarlatina type changes Recalls the case of a physician who had not had one death among fifty cases of the disease and immediately afterwards lost his own child with it The local treatment is important because it destroys the micrococci and prevents septic poisoning, Septic absorption occurs where the membrane invades the cells of the mucous coat Uses in nasal diphtheria

℞	Sodium chlorid	ʒi
	Acidi Boracici	℥ss
	Aquæ	Oi
Or,		
℞	Hydrarg Bichlor	gr ii
	Aquæ	Oi

What is to be done in diphtheritic croup? Tracheotomy? No Dreads to be called to these cases No irritating substances, such as bromine, should be employed on such surface, as they only extend the inflammation Has found the alkalies good in breaking up the fibrinous membrane Alkalies disolve both fibrine and mucin Great benefit is found in watching for the hoarseness and commencing treatment at once, and mothers are instructed to be on their guard about this Use steam atomizer with liq potassium, ʒiii, strong aqua calcis, Oi

Dr Burrows, Ill , agrees with Dr Smith, but employs sulphur for insufflation, as there is danger of the nasal injections producing otitis media It also has some effect on the blood corpuscles

Dr Harris, of Va —Results claimed for treatment are much better than Virginia gives In the epidemic two years ago three-fourths died They were in a state of collapse from the beginning, and never rallied The regular treatment was adopted This is the dark side Then, on the other side, all cases recover without treatment These were typical cases In only a small proportion of the cases is the larynx affected Spasmodic croup can be mistaken for true croup and diphtheria Has seen two cases cured by Pepper's treatment

Dr Miller, Allegheny, Pa —The thirtieth of a grain of bichloride of mercury given every hour softens the membrane when the remedy acts Pay attention to the well Examine every day In his own family pilocarpine had a good effect Also the permanganate of potassium acts well locally

In the County Orphans' Asylum has not used a pint of alcohol during some years, but gives milk in large quantities

Dr S C Busey, D C —There are three forms of the disease The first can only be recognized by the resulting paralysis The second can be recognized and treated The third all die

Mistakes are made frequently, the simple can be converted into the severer form There are more deaths from the disease in country towns and more deaths where the simple (catarrhal) throat troubles prevail It is both local and constitutional, for data from the census reports show that it is not always constitutional In Virginia the cases were dead from the beginning Certain number of local cases can become constitutional Local treatment is very important Dissolve membrane off first, and then apply oleate of mercury Solution of nitric acid, 1–3, or spray 1–5, best to remove membrane No case lost where this was done Support with milk and beef tea The former best Internally give chlorate of potassium, tincture chloride of iron, and alcohol

Dr Ulrich, Pa —Did the doctor make a distinction between diphtheritic and membranous croup?

Dr S W Smith —The latter is distinct from diphtheria, but during an epidemic, diphtheria can have diphtheritic croup engraved on it

Dr Ulrich —We can have both diphtheritic and membranous croup The treatment is different Has not changed treatment in diphtheria since an epidemic seen in Louisiana a number of years ago, 13 cases died at the outset of the epidemic Had good results with large doses of chlorate of potass and tincture of chloride of iron Does not neglect local treatment, but does not rely on it It is difficult to use anything Muriatic acid and honey is a good application Physicians do not use enough of iron in these cases Large doses of calomel have been given, acts same as the bichloride of mercury

Dr Free —Is not chlorate of potassium injurious in large doses? Has seen several deaths from it, due to kidney complication It is considered good treatment in his county to save 80 per cent Uses stimulants at once in large doses Tincture of the chloride of iron is used, but omits quinine No reason for it except that it disturbs the stomach and has slight antiseptic effect No deaths from diphtheritic laryngitis in his county Milk and beef tea (home made and Johnson's) employed Always uses constitutional and local treatment Meets with paralysis in all cases In answer to question said that he used half to two ounces of rye whiskey every two hours

Dr Hicks, of Virginia, said cases of diphtheritic laryngitis were all fatal About two cases usually occurred in an epidemic Treatment depends on theory Diphtheria cannot arise from catarrhal diseases, but the latter can predispose to it Like only begets like Why do physicians prescribe chloride of potassium and the tincture of chloride of iron? As antiseptics? Sepsis does not occur until late in the disease Chlorate of potassium is very bad for the kidneys The disease can be divided into three types

1st Mild cases All get well We do not know how the disease does when left to itself Formerly, pneumonia (an inflammatory disease), when actively treated, gave a mortality of 30 per cent Now, when left to itself, there is only a mortality of 5 per cent

In the second class certain ones can be cured with food and tonics Germicides are to be used

In the third class all die Severe treatment does no good

Mild solution of chloral good Quinine also good for fever The disease cannot be studied in country practice, because there active treatment must be resorted to or else the patients employ some other physician

Dr Holton is a firm believer in the contagiousness of the disease Gave several examples to illustrate this How is the poison of the disease carried? It can be conveyed after recovery, and without the person conveying it having had it Formerly thought it to be a constitutional, but now believes it to be a local disease Germs accumulate and fructify on the mucous surfaces Believes in local treatment This depends on form In 113 cases there were 13 deaths Two deaths in cases not treated Nine of the other eleven were treated by Homœopaths Where there was no treatment death resulted

Uses chlorine as recommended by Watson, but stronger Believes in whiskey but not in quinine The latter acts upon the blood corpuscles, and these are not affected in diphtheria Can be of service later on in the disease by its effects on the lymphatic system Stimulants are necessary

Dr Hicks, of Vermont, believes that it is contagious, and gave examples Circumstances modify its contagiousness

Dr Park, Dauphin Co, Pa — There are many cases of diphtheria where no communication has taken place Death is rare, except from diphtheritic laryngitis A gargle of tannic acid, carbolic acid and glycerine is in general use Does not believe in contagiousness

Dr Wm Lee, Md —Success depends on the diagnosis Nothing is so difficult as to diagnose diphtheria from catarrhal angina Never call a case diphtheria, unless both tonsils are affected or patch extends behind uvula, or pharyngeal folds Both tonsils are very soon affected. In diphtheritic coryza the secretion microscopically shows all the elements of diphtheria. Employs resorcin locally and constitutionally, instead of alcohol. Does not believe in mopping the throat. Has seen children die in the arms while being mopped. Treats all cases as contagious.

Dr. Ulrich, Pa.—The pharyngitis can be the first stage of diphtheria. We cannot make a distinction at first. It cannot culminate in diphtheria. The latter is constitutional, the former not.

Dr. Busey.—Cannot diphtheria be engrafted on pharyngitis?

Dr. Ulrich.—Yes. The latter can be the starting point. The system is contaminated with the diphtheritic poison.

Dr. S. W. Smith.—The distinctive sign is that the deposit in pharyngitis can be washed away, which cannot be done in diphtheria. Does not believe the disease to be contagious. There is no danger of ear trouble in washing out nose.

Dr. Brown.—The paper was to show the good effects of the sub sulphate of iron in diphtheria. Regards hoarseness as a valuable sign of diphtheritic laryngitis. Has found vinegar a good solvent of the membrane. Temperature curves are valueless. It is a constitutional disease, and tracheotomy has been fatal in all cases where it was performed. But the patients had an easier death. Has had no experience with the bichloride of mercury.

ON ASSURING HEALTHY DENTINE OVER ENDANGERED PULPS.

BY JACOB L. WILLIAMS, M. D., BOSTON, MASS.

Read in the Section on Oral and Dental Surgery of American Medical Association, May, 1884.

In saying endangered pulps I mean cases where the pulps have but little of the natural covering of dentine in the depths of cavities, which covering is very apt to be more or less tainted by disease, that is by the agents that have produced caries.

Let us look at the conditions here existing. There is acid with fermentive action, often in full sway, seeming at first sight to demand the most decided and effective neutralizing and corrective applications. But, just beyond lie some of the most highly and delicately organized tissues of the whole body, fibres, that if rudely set vibrating will be likely to continue or repeat their vibrations in a very serious way, tissue, which if inflamed, there is none more doubtful of survival, and we must remember that the life of the pulp means additional years of usefulness to its organ.

These circumstances I fear are often too little considered in the use of violent or caustic applications.

But what should be done? Perhaps my ideas on this point may be best given by mentioning a plan of treatment for such cases that I formed, tested, and adopted during the years 1847 and 1848, and which in its general principles I have found to be most satisfactory up to the present time. Of course, since that date new materials have been added to our list of available correctives for diseased conditions.

After first removing the loosest débris, I applied a mild antacid such as aqua calcis or a solution of bicarbonate of soda, after thorough saturation with which, I treated the cavity for the correction of fermentive elements by the application of a solution of chloride of calcium, also very dilute creosote (we now have several substitutes for that). The cavity was then dried and sealed up for from two to three weeks, when it was opened and the *mild* saturation repeated, adding perhaps a mild astringent, such as tannic acid in weak solution, to the latter application. Then it was sealed up again, generally for a longer period, and the dressing was repeated at proper intervals until permanent health of dentine was assured.

Now with these mild correctives we have a greater chance of avoiding undue irritation of the pulp than with stronger applications; but they will be more or less transient in their effect, and therefore will require frequent repetition, which may be less frequent as the dentine gains in soundness and health.

By this method we help nature in the line of her preference, that is to protect rather than injure a vital point, keeping the disease in check to give her opportunity.

It may be, and has sometimes been said, that this treatment is very troublesome, and, why not make one strong application, and trust that nature will do the rest? I reply that the great objection is that while a strong or caustic dressing is not always lasting in corrective influence, it adds vastly to the possibilities, if it does not make sure, that the reparative action of the pulp will be interfered with, resulting in failure of the ultimate object of secondary deposit. Instances of this sort are often seen in practice; and in my observation the proportion of success of the mild repetition plan is far beyond that of the single capping practice.

Of course there will be some chance of non-success in many attempts to save the pulp, depending often on constitutional as well as local causes, and both may be obscure. The best and most promising efforts may be thwarted by neglect of the patient to report at proper times, or by interruption of the general health. Or, again, when cases are nearly ready for a permanent operation, they may be piratically appropriated by some person who very probably will speak lightly of the treatment that has brought the teeth into condition for his profitable seizure. But still our highest duty is to save life rather than to destroy or endanger it.

Representative cases might be related from a large number with various phases, but to describe them minutely would task both your time and patience.

Plaster of Paris was first used as a cap for the exposed portion. Oxide of tin was also mixed with the gutta-percha.

One rather extreme case I might mention, occurring in 1854.

A young man aged 25, upper left first molar having a large and deep cavity on the mesial side, with the pulp covered only very thinly by softened and disintegrated remains of dentine

But the pulp was apparently uninjured, and on inquiry I found there had been no pain, and nothing to indicate the existence of inflammation in any degree, which was an encouragement to give the pulp every chance to live and protect itself by secondary dentine

I saturated the cavity first with aqua calcis about half strength, then with solution of chloride calcium, but this causing slight sensation I reapplied the aqua calcis with the effect of stopping pain

I then applied a *mild* non-irritating antiseptic in proportion about as follows, viz a wood creosote (at that time the best known antiseptic of its kind), one drop to one drachm of alcohol, adding two drachms of water, after which I dried the cavity and covered the depth over the pulp with a mixture of oxide of zinc, five parts to one of gutta percha mixed with its bulk of yellow wax, over which I placed carefully, without pressure, and filling up the cavity with the gutta purcha and oxide of zinc mixture, melting the wax After two months I unsealed the cavity, repeated the antiseptic with the addition of a trace of tannic acid, this at first caused sensation which was readily dispelled by aqua calcis I then dried and sealed up the cavity, at the end of four months repeating the above treatment, twice again after six months, and finally after about eight months, making more than two years in all, when there was a firm, hard almost transparent floor of new dentine, from which the former disintegrated material was readily brushed off by a light touch of an instrument After placing an inert non-conducting material (a piece of fine white silk saturated with wax) at the depth of the cavity, I filled with gold Two years afterwards a small cavity occurred on the distal side of the same tooth, which on preparing to fill I found as sensitive to the instrument as if it had been the first cavity the tooth ever had, proving the unimpaired vitality of the organ, which continued several years after and during the life of the patient

DISCUSSION

Dr W W Allport, Chicago, Ill —Was certainly very much interested in the paper, and the line of treatment mapped out by the author It has been the usual practice to apply antiseptics in these cases, creosote, carbolic and eucalyptus, etc , in various strengths and then to immediately cap with some non-conducting material like gutta percha, oxychloride or oxyphosphate of zinc

The first important point to be gained is to neutralize or destroy the agents of decay, and then to protect the pulp from irritation of every variety

This can best be done by using a non-conducting material directly over the pulp and then to fill the balance of the cavity with a substance sufficiently hard and firm to prevent irritation from mechanical pressure, but do not see why the treatment need be continued over so long a period as that practiced by Dr Williams

Dr J L Williams —The object in continuing the treatment over so many months is to be sure that the active causes of decay are destroyed or rendered inert, and to guard against pulp irritation by frequent dressing with mild remedies, rather that to run the risk incident to the application of such intense medicaments as are commonly used

Dr Allport —I have heard something recently about a new remedy for the treatment of this class of diseases made from the oil of cloves, and known as eugenol It has been very highly recommended as having a decided fatal influence over germ life

Have had no experience with it myself, but would like to hear a report upon the subject from those gentlemen who have experimented with it

Dr A W Harlan, Chicago, Ill —Dr Williams spoke of his treatment being to antagonize the acid or acid ferment Such treatment could be only of temporary benefit, the remedies must be of sufficient strength to destroy the agents of fermentation Most practitioners are in the habit of swabbing the cavity of decay with creosote, carbolic acid and other like remedies, and after temporarily sealing it up for a few days, capping with gutta percha solution, oxychloride of zinc, metal caps with various forms of dressing placed upon the under surface and permanently filling the cavity of decay But in such cases we have no means of knowing whether there has really been any deposit of secondary dentine, and I believe in a vast majority of them no secondary deposit occurs

---

FRAGMENTARY COMMENTS ON SOME OF THE PRINCIPAL METHODS OF OPERATION FOR "STONE IN THE BLADDER"

With Special Reference to Allarton's Method, Also in Combination with Lithotripsy, Urethro-Lithotripsy, Urethrotomia Lithotriptica, Including Besides Critical Remarks Upon the Discussion of the Progress Made, in Lithotripsy and "Lithotomy" at the Late International Medical Congress held in London, England, and divers other subjects comprising the Urinary Organs

BY M SCHUPPERT, M D , OF NEW ORLEANS, LA

[CONTINUED]

The high recommendation of litholopaxy was no doubt also influenced by "avoiding the bloody knife," though we have seen that even Sir H Thompson recommended a combination of the two methods, "lithotripsy and lithotomy," neutralizing thereby the highly praised distinction and benefit attained by the exclusive adoption of litholopaxy

How different all of this becomes in selecting the operative methods of Allarton, in the inestimable boon of which method the risk of the so much feared "bloody knife" is reduced to a mere myth, in which the bladder is secured to remain even more intact than in Bigelow's litholopaxy, and with which it shares all the benefits if combined with lithotripsy! Well may we say that by the nearer and better access to the calculus, by its total removal, either entire or in combination with lithotripsy, of even the largest calculi with the more complete, surer and quicker withdrawal of its fragments, and displacement of that element, which renders also Bigelow's operation still dangerous, *the urine*, the pærineal median urethrotomy of Allarton stands to day inferior to none of all the diverse methods of cystotomy, litholopaxy not even excluded That mentioned danger from the urine, including the feared recidives of phosphatic concrements—of both more at a later time—have also induced even admirers of Bigelow's method to declare "that after all, nothing was won by it" The crushing of big and hard stones, if necessary, by the introduction of the respective instruments through the pærineal wound, instead of carrying them through the whole urethra, will also permit to build the instruments much more solid and powerful, so that they will not act at the beak only, which is still a defect in Bigelow's percuteur The knife finally causing merely an incision through the urethra, will equally be deprived of its "bloody" and "dangerous" character Of all the partakers in the discussion of the main subject under consideration in the International Medical Congress, there was not one voice heard in opposition to the dictum of the presiding officer regarding the operation of "lithotomy" It was as if the enthusiasm for the American operation had swamped all other questions I am, indeed, far from objecting against a well founded enthusiasm, and less so in view of the merits of our own Bigelow, but the assertion that "we had nothing to show in the progress of the knife in that field," was an injustice toward those surgeons who had proven by their success that there was at least one, if not another, method well worthy of a special consideration and support

The only preparatory manipulation Allarton's method has in common with Bigelow's operation consists in the dilatation of the urethra, but with the exception that in urethrotomy strictures, which would render the introduction of lithotriptic instruments impossible, would here seldom interfere The urethra, or that part of it from the opened membranous portion to the neck of the bladder, will permit a far greater extension, and without causing the least laceration, than *Otis'* measurements would seem to warrant In my last operation after Allarton's method, I removed a calculus of near half an ounce weight, the circumference of which, including the branches of the fine polished forceps, measured 82 mm , and the extraction of the calculus was performed without the use of any extraordinary force, and without laceration of the parts Among the main objections against this median cut stands the statement that no further dilatation of the prostatic portion of the urethra beyond 50 or 60 mm was possible, and that any further efforts of dilatation would produce laceration (*Ellis, Teevan*) That statement I may conscientiously contradict, since in my operation not a drop of blood followed the extraction of the stone, which in case of a laceration might certainly have been expected Not even the finger, introduced into the urethra, presented a trace of blood That in case of a previously diseased urethra, or of the prostate, in strictures, or by a rough handling, such lacerations might happen, I will not deny, yet we know from the experiments of Simon to what an extent and in what short time, by a careful and gradual dilatation, the lumen of the female urethra may be enlarged without committing any harm to that organ The male urethra will certainly not much differ in that respect from the female one

The operation of Allarton, we are informed, originated from a method known under the appellations "*Methodus cum apparatu magno*," which was invented in the year 1520 by a surgeon of Cremona, Italy, *John de Romani*, who communicated it to one *Mariano Santo di Berletta*, since which time it became known under his name *Mariano's operation* It became obsolete, but was revived, though greatly modified, by Allarton, and like Bigelow's method of lithotripsy, became a totally different operation from that of Mariano's While the latter operated *on the left side of the raphe*, not sparing the neck of the bladder, and making use of a multitude of superfluous and odd instruments, which gave the method the name, "*cum apparatu magno*," Allarton operated exactly *in the raphe*, opening only the membranous portion of the urethra with the knife, and dilating the balance of the channel with the finger The instruments were but a few, mainly a sound, scalpel and and forceps While there existed many objections against Mariano's method, in consequence of which it was most properly relinquished, the method of Allarton, which is still often and very improperly mingled with Mariano's, by its virtues deserves well the ascendency assigned to it Its reintroduction into Germany belongs foremost to that illustrious surgeon R Volkmann, of Halle, Prussia, one of whose last statements, in reference to that operation was "that during the year he operated in the average on eight cases of calculus," and that "*there had to be most extraordinary circumstances, if he should select another method than Allarton's*" In order to give a thorough discription of Allarton's methods, I have selected here a typical case

Pærineal median Urethrotomy Allarton's —The subject of this operation was G Cook, 22 years of age, a native of this city and of German extraction He measured 5 feet 4 inches in height, weighed 117 pounds, with a skin of fair complexion and light brown hair He had been, according to the statement of his mother, a sickly child and was once reduced to a mere skeleton His mother had given up hope ever to raise him When 4 years old his urine became "bloody" with "sandy deposits," which condition lasted with few intermissions nearly two years The boy often suffered a great deal of pain All of these symptoms disappeared when 6 years old From that time, against all expectation, the boy grew strong and healthy With the beginning of the year 1878, when 20 years old, the symptoms characteristic of the presence of stone in the bladder set in According to his own statement he was examined by several physicians, yet all but one had failed to make the correct diagnosis of his ailment I first saw and examined him in 1880, discovering a calculus of about the size of a ripe walnut I proposed to him the operation, to which he gave his assent

From the history just given it was more than probable that the calculus was originally renal and having arrived in the bladder became fastened in a diverticle, where it remained growing till the attained weight caused its displacement Out of its confinement, it became from that time, a troublesome lodger

Previous to the appointed time for the operation I took proper care that the urine presented a distinct acid reaction He drank some alkaline waters, citrate and tartrate of potassium, for several weeks On the day of operation the presence of the calculus was once more established by the stone sound and bimanual exploration, in inserting the longest finger of the left hand in the previously cleaned rectum, while the right hand pressed against the abdomen The diagnosis having been again corroborated and the size of the calculus once more explored, I met with no prohibitory cause for performing Allarton's method, as originally intended It may be as well to state here, that previous to deciding upon this operation the urethra ought to be well examined if no obstacles exist to prevent a proper and sufficient dilatation of that channel, which if existing, have of course, first to be removed before the operation can be undertaken

On the morning of the 30th of October, after the patient's bowels had been moved by a cathartic on the day previous, and again one hour before the operation by enemas, he was narcotized with chloroform by Dr Schmidthe When fully under its influence the patient was placed on a table in the known position for cystotomy With the lower extremities bent at the kneejoints, the hands kept tied to the feet and his *posteriora* brought close to the edge of the operating table, projecting rather a little beyond it, I took the surgeon's perilous position between his legs I say "perilous" in having learned from former operations of that kind, that no reliance is to be placed in any security against involuntary discharges of the bowels, though they may have been thoroughly cleansed previously —Such *involuntarii alvi secessus* I have also observed to happen, notwithstanding the same precaution in splitting fistulae in ano —The precaution I had taken against such an accident proved to be a wise one The pærineum after being shaved, was cleaned with alcohol vini, followed by washing the parts with phenol water of 3 per cent The instruments had also been cleaned and were kept in phenol water of 5 per cent like the new sponges which I here used exceptionally My son William took a position to the right of the patient, holding the itinerarium, which I had introduced, steady in its place with his left hand, while with the right he kept the scrotum elevated against the symphysis pubis Whilst the itinerarium was held exactly in the raphe of the pærineum I made the incision The point of the scalpel was inserted in the raphe at the beginning of the pars bulbosa urethræ, cutting downwards in the raphe and ending about 12 mm (½") distant from the anal aperture Having divided the cutis and the superficial fascia, the groove in the staff could be distinctly felt In cutting down upon it the membranous portion of the urethra was laid open A portion of the hæmorrhoidal veinal plexus was hereby cut, but the bleeding was trifling, and this was in fact the only blood lost in the operation Not that I place any weight upon the loss of blood in operations, if not in excess The present mania of saving every drop of blood in operations, I consider just as manifestly an error, as in former times blood letting was in a Sangrado fashion The proceeding with the operation was therefore not even interfered with momentarily The cut in the urethra measured nearly three ctm in length The prostate, which I had explored previous to the beginning of the operation, was not touched by the knife, and the knife was abandoned for the balance of the operation after the urethra had been laid open In beginning to dilate the urethra towards the bladder, I made first use of a dressing forceps to initiate the dilatation before using the finger Volkmann at this part of the operation recommends to remove the staff and replace it by a probe I tried it, but soon found that the finger rather lost its direction, instead of being supported by the slender probe I therefore reintroduced the staff The single difficulty here met with consists in first entering the finger into the urethra, but introducing the dressing forceps closed, led by the grooved staff, and opening the branches of the forceps in different directions, that difficulty will soon be overcome and sufficient room be gained for entering the point of the index finger Once thus started I soon succeeded by a rotatory motion of the finger to enter the bladder Another support of accomplishing that maneuvre consists in placing one hand on the abdomen of the patient above the symphysis pubis, causing a moderate pressure towards the rotating index finger of the other hand in the urethra, whereby less difficulty is experienced, nor is the bladder pushed out of the way On the contrary, the bladder is thus, so to say, stripped over the encountering finger like a glove After the finger had once entered the bladder, the staff was removed for good The dilatation of the urethra was gradually accomplished, when the well polished branches of the stone forceps were easily carried into the bladder

The calculus was known to be of an uneven, rough surface, presenting many protuberances Of these I fritted away a good many to decrease the diameter of the calculus in extracting it I might as well have made use of the percuteur and crushed the stone, but I felt confident to extract it entire, without causing any laceration After some ineffectual attempts in grasping the stone at its smallest diameter, I finally succeeded The stone was extracted without any injury to the prostate, or laceration in the least of the urethra

The calculus belonged to the so called mulberry variety Its two diameters measured 26 and 33 mm The circumference of the branches of the forceps holding the calculus in its smallest diameter measured 88 mm (3½"), while the circumference of the stone, at its smallest part, presented 75 mm , and 89 mm at its largest Its weight was not quite half an ounce These measurements may prove the degree of extension the urethra can suffer if slowly and carefully dilated It is considerably greater than Otis has given as the normal circumference (as we will see hereafter)

After the removal of the calculus, the bladder was repeatedly well washed out with 3 per cent phenol water, and the wound kept covered by carbolized sponges, fastened by a T bandage The sponges were daily exchanged, boiled and kept in 5 per cent phenolwater till used

After the bandage had been removed from hands and feet, patient was carried to bed and ⅙ grain of muriate of morphia given subcutaneously He was still under the influence of the chloroform, of which about 4 ounces had been consumed [1] At the evening visit I found patient perfectly serene, not having suffered any pain, nor even the common nausea from the chloroform

On the next morning visit the wound looked well, no hardness or swelling, to any extent, was perceptible, nor had any bleeding happened Though a good deal of micturition had set in, little urine passed through the wound that day The urine was limpid, pulse 130, temperature 101° F , which condition lasted during the first three days, excepting the pulse, which diminished 10 beats on the second day There was no fever at any time, and I assigned that phenomenal rise more to the action of the chloroform than to the operation or any of its consequences On the third day pulse and temperature had become normal After the second day the urine came away from the wound still in drops, which lasted during several days, when it ceased abruptly On the morning of the fifth day I found the temperature increased to 103° F , and on examination became convinced that the aseptic treatment had become defective by the nurse's fault The sponge at the wound was dry This was immediately attended to, and on the seventh day, at the morning visit, the temperature was again normal, and remained so till the wound had totally healed During all this time the patient had been in the best of humor From the fifth day after the operation, most of the urine was discharged through its natural passage, and from the eighth day, all of it Only when the bladder became overfilled did a few drops of urine pass through the narrowed opening At the end of the second week the wound was filled up by granulations, and cicatrization began The patient left his bed, and with the end of the third week the wound had totally healed

I have been led to believe that an operation causing so little reaction, being free from any danger, in fact presenting so favorable results, ought to recommend itself to the proper regard and patronage of the surgical profession I have no doubt of the pærineal median urethrotomy making friends wherever it will be once tried, and the eminent surgeon of Halle deserves praise for his zeal in having assisted so powerfully in the reintroduction of a method which, for so long and unjustly, had been consigned to the lumber-room [1]

How singular, then, must it not appear to see Erichsen confound the two operations, that of Allarton with the obsolete method, Mariano's two operations which have nothing in common but the general field for operating—the pærineum, beyond this every element, every part of the operation differs While Allarton, as already mentioned, selected the raphe, Mariano operated outside of it Allarton opens only the pars membranacea of the urethra with the knife, dilating the balance up to the bladder in a gentle manner by the rotating finger, leaving thereby uninjured the vas deferens and the calliculum seminale Here an operation which needs but a few instruments, while Mariano, on the other hand, operated with a most complicated instrumentarium purposely constructed for it, forcing open the wound *vi et armis*, tearing and lacerating the prostate and neck of the bladder, and injuring thereby the seminal vesicles, an operation suspected of causing sterility and followed by a high mortality, an issue totally unknown in Allarton's method True, when Allarton about twenty years ago introduced his new median section, it recalled to mind Mariano's old obsolete operation of 300 or 400 years past, but that such could induce an Erichsen to remark that "Allarton's method was a reintroduction of Sanctus Mariano's operation" and that it afforded him an illustration of "the mutability of professional practice," which made it appear that there was "a cycle of opinions of fashion in surgery, as in politics and philosophy," is more than I am able to decipher If such material differences of two methods, as we have seen here, entitle an author to call one "the modified modern," the other "the old method," then one might as well count the Cæsarian section amongst the modern and fashionable forms of delivery

Erichsen, in his latest edition of '*Science and Art of Surgery*,'' has proposed a modification of Allarton's method, but I doubt if he will thereby give more satisfaction and greater security, or render the procedure described above easier of execution In his exchanging the curved staff for a rectangular one, with its lower end 2½ ctm long, with which length the incision has to correspond, cutting upwards, with one finger in the rectum, to secure the latter against being wounded, I really see nothing to admire as an improvement, but rather what the Germans call "eine eselsbrucke"—an ass bridge. Besides in employing a finger at intervals in the rectum is not well compatible and in harmony with the idol of a perfect asepsis and a scrupulous cleanliness. And again, from fear of wounding the rectum to give the advice to cut away from it in an opposite direction, would but prove the utter unfitness of a surgeon who would commit such a blunder. Such a person had better select another occupation, exposing himself less to become wrecked in reputation.

---

[1] It has become a principle with me, based upon an extensive experience, to prefer chloroform to ether and never begin an operation before a deep narcosis has been obtained I rather sacrifice some ounces of chloroform of which I apply always the purest and dearest (made from hydrate of chloral raw) than risk the life of my patient by depriving him of a sufficient quantity of air inhaled with the chloroform vapors The habit of using minimal quantities of chloroform measured by drops under a total or near a total exclusion of the atmospheric air which produces *asphyxia* instead of *anæsthesia*, is a practice which cannot be condemned too severely I have administered chloroform over two thousand times and used more than two hundred pints of that liquid and never met with an accident produced by the chloroform *which I had not been able to remedy by my method, in reversing the whole body of the patient* as soon as threatening symptoms happened, in a cessation of respiration and circulation setting in Such happened five times during my thirty four years of practice and in no instance did the method fail me The only author who has mentioned my method properly and experienced its efficiency was the late Prof C Hueter, in his Grundriss der Chirurgie Allg Theil page 470

[1] That a method apparently so free from all danger may nevertheless, end fatally I witnessed this year Though the operation itself had been performed in a bungling manner it was the neglect of a properly applied asepsis which caused pyæmia and death

The enlarged incision of the cutis and subcutaneous cellular tissue in the raphe beyond the necessary length, I prefer on account of enabling the surgeon afterwards to dilate the urethra easier and more extensively. Pushing out of the way the bladder whilst dilating the urethra with the rotating finger, which, singular to say, has given Erichsen cause for complaining, and in which he sees even a point of accusation against the method, is too trifling an obstacle for a practical operator and what, as I have shown, may be obviated in the most simple manner by pressing with the non-operating hand against the abdomen, by which the neck of the bladder will, so to say, be pushed over the rotating finger of the other hand, assisting thereby the surgeon considerably in accomplishing his object. It must indeed be a well fortified method against which no more serious and graver objections than such trifles can be brought, to demolish it or bring it into discredit.

It is astonishing how easy and by taking time, to what an extent the urethra can be dilated after a beginning has once been effected. We meet with the same capacity in the female urethra, the uterus and the rectum, into which latter, with care, the whole hand and even part of the arm may gradually be introduced without producing a laceration, or, subsequently, a paralysis. The important condition of the urine, its innocence, if of an acid reaction, and the noxious influence on the other hand, if of an alkaline nature (which we will hear of later) and which ought always to be taken in consideration before deciding on a traumatic operation comprising the urinary tract, seems also to have been ignored by Erichsen. How much ignorance or oversight in that respect has had to do in judging the comparative value of one or the other method, who can tell?

The perineal median urethrotomy, then, compares no doubt favorably with all the other methods of operation for stone in the bladder. The apparently small room the urethra offers for manipulating and extracting stones may to the inexperienced be an apriori justifiable objection against the method, and the surgeon who has never experienced to what a degree that channel can be dilated, will hardly believe that most of the stones removable by the lateral section, without crushing, can also be extracted by the pærineal median urethrotomy. Its disadvantages, if there are any, compared with the advantages are of a minimal character. The small wound, the trifling loss of blood, security in the knife's direction without any danger of wounding neighboring organs, and the short time necessary for a final recovery of those operated upon are almost unknown as an ensemble in any other method. How much advanced and improved, however, the operation of lithotripsy may have become of late, in complications with those fearful conditions cystitis and pyelonephritis, Allarton's method with its effective after treatment will occupy the front rank in the operation for stone. In few surgical operations has the human ingenium so well succeeded in obtaining its object and in delivering the human race from one of the most loathsome diseases to an extent almost beyond further improvement. In the face of this assertion then, vindicated by incontrovertible fact, it must appear strange to come across so singular and retrograde a proposition as the median operation has experienced in Berlin, Prussia. Instead of operating in the raphe as in Allarton's, the old obsolete Mariano's method, selecting the left triangular space near the raphe, has again been chosen. The only reason those surgeons have advanced for this poor innovation consists, that in case of too large a calculus, in order to win further room for the stone's extraction the lateral section might be added. That this modification has all the disadvantages and dangers of the properly relinquished method of Mariano, need not be further demonstrated. Why in such a case of too large a calculus a resort is not taken to the percuteur, or, even an extension of the incision towards the neck of the bladder in the direction of the raphe, is more than I am able to comprehend. The innovation is, to say the least, little creditable to its author.

To neutralize the bad impression the Berlin proposition must have caused, I will place here a practicable hint relating to the initial steps of Allarton's method, introduced by the late Dr. Wilms, of Berlin. He brought a kind of forceps, with two smooth branches, into the urethral orifice, and when arrived at the *pars nuda urethræ*, the instrument is partially opened, and between its two branches the incision perfected, dividing the parts to be cut all at once, and with perfect security. The ever-practical Wilms recommended the instrument highly.

After this exhaustive description and analysis of Allarton's urethrotomy in favor of the uninitiated, it is left to me to speak of its combination with lithotripsy, to which I have applied the name

Urethro lithotripsy—Urethotomia lithotriptica.—In returning here once more to the operation of lithotripsy, such has been caused by reflecting on some historical points concerning that operation, by Dr. Ed. Keyes, of the Bellevue Hospital, in New York. That author, in a studiously collected history of the operation of lithotripsy, tells us that attention to that operation had first been incited by the success of Civiale in France in 1824, and whom Keyes calls "the Fulton of lithotripsy." The successive sittings of crushing the stone did not last longer, as stated, than three minutes, after several days' rest. In a pamphlet written by Civiale in 1847, he claimed, of sixty-nine cases operated upon by himself, to have suffered only three deaths. But we have learned what to think of Civiale's statistics, which become the more suspicious here when we are made acquainted with the length of time the fragments were left in the bladder, considering, moreover, the inadequate and deficient instruments used at that time, not to speak of the unknown action of the urine in complicated cases, nor of the known insalubrity of the Parisian hospitals Next to Civiale, the French had two more distinguished lithotriptists at that early time—Leroy d'Etiolles (1846) and Heurteloup The first asserted to have operated over 100 cases with success Rapid operating, with immediate extraction of the detritus, had already, at that early time, become the *beau ideal* of that method The bickerings amongst the surgeons at that period were so great "that it may be considered a wonder," says Keyes, "that lithotripsy ever succeeded in becoming established as a justifiable surgical procedure " That state of affairs gives us also a hint what to think of the published statistics at that period It was Heurteloup who introduced the method into England (London) And in London he also published some of his writings (1831) Heurteloup, singular to say, stated it to be unnecessary to remove all the detritus, and that after the removal of the coarser particles, what was left would dissolve in the urine (!) Indeed, a strange idea, which Keyes properly characterizes as "an arrant heresy to damn lithotripsy at its birth " But when Keyes further adds "It being clear that rapid lithotripsy, as performed by Amussat, Leroy d'Etiolles, and others, had been an unsurgical procedure, which could not stand the test of experience in the hands of the general surgeon," he evidently unwillingly committed another and not a smaller heresy, notwithstanding that rapid lithotripsy disappeared to a great extent, and "even Heurteloup had given it up at the end of his career " I am at least at a loss to conceive why men like an Amussat or Leroy d'Etiolles should have insisted upon the early removal of the fragments, if they had not had an adequate reason for it, nor can I comprehend upon what motive Keyes condemns that procedure, since, under an entire absence of all antiseptics at that time, the total and rapid removal of all the detritus could only have vouchsafed a successful result And most so would it have been afforded in complicated cases, as with cystitis, even when the pain caused by the fragments should not have called for it To no other action, at least, could I attribute the good results, provided such had in verity been obtained

That even at the present time a wrong conception exists among the majority of surgeons about the real injurious influence of the fragments of stone, may be proved by the neglect of insisting upon its early removal and a thorough and repeated washing out of the bladder with antiseptic liquids which will be demonstrated in the following

Keyes' paper informs us further "that in London at the time of Heurteloup's arrival scattered accounts of rude operations of lithotripsy had existed, but that it finally had gained the sturdy advocacy of H Thompson, who had become its apostle and recognized authority " "That Thompson had declared it the *exclusive* operative procedure in *small stones* That the best English surgeons at that time had been in favor of lithotomy, reserving for lithotripsy only such stones which might have been removed in a few sittings, and when the bladder could have been promptly freed from the detritus " "Matters had stood about at the same level in this country Lithotripsy had had but few serious supporters But a new departure had taken place since Bigelow's litholopaxy had gained favor here as well as in England under Thompson's leadership, and which had forced lithotomy into a position of minor importance "

"Entire fragmentation of the stone," says Keyes, "with immediate and total removal of the débris by aspiration through a tube passed by the whole of the urethra is the proper definition of *litholopaxy* But that Bigelow disregarded the length of the time employed in the operation so long as the patient's general condition was as good as he desired "

"There is nothing new under the sun " the rabbi Ben Akiba once remarked To detract from Bigelow's reputation, so that he should not pride himself of his well-earned triumph unimpaired and uncurtailed, Keyes tells us, an Englishman had been brought upon the boards, claiming for himself the priority of the principles advocated by Bigelow Stokes, of Dublin, in December, 1879, stated before the Surgical Society of Ireland, that Bigelow's operation had already been performed in the Meath Hospital, in 1845, by Sir Philip Crampton Stokes, in presenting even the original instrument, claimed that the principle of its action was the same as Bigelow's Keyes well remarks here "that it ought not to be forgotten that Sir Crampton's instrument had been used for an atonic bladder and not for a healthy one, besides there had been already surgeons like Carney, Mercier and others who even before Crampton had used similar instruments Mercier's instrument had even the same rubber bulb and a similar glass receiver as Bigelow's, but all these were used for other purposes than Bigelow's

After this short historical and interesting sketch, I turn again to the combined operations of urethrotomy and lithotripsy The operation may also be called an infringement, since the urethrotomy is Allarton's and lithotripsy its inventor's But while both methods separately are mainly recommended for comparative small stones, I, on the contrary, claim its application exclusively for the largest and hardest calculi, whilst for the small and middle sized ones Allarton's method ought to be the favored one almost exclusively

After the exhaustive description of Allarton's operation—yes, what has been said of both operations—there is no need of further explanation The name represents that sufficiently Nevertheless, as will be observed, there are some particular points still to be argued here which may not be bare of all interest The advantages of the combination of both operations are obvious The crushing instruments, the lithotriptor or percuteur, can be built in a far more solid manner than when it has to pass the whole urethral channel, in consequence of which much larger and harder stones could be crushed than such as would be obtainable with the lighter constructed instruments, even Bigelow's not excepted Next to the crushing of the stone, the removal of the detritus can also be accomplished more completely and in a much shorter space of time, since those fragments need not be brought into so fine a dust as necessary to enter the eyes of the catheter In the removal of the detritus, a common small glass or metal tube and a syringe will answer for Bigelow's sound with aspirator The complete evacuation of the bladder from the débris of the crushed stone in the smallest compass of time, is evidently preferable to short crushings at longer intervals, as in Bigelow's method, where from 5 to 16 grains of the débris for every minute in an acid urine, and 2½ grains in an alkaline urine, and in the presence of phosphatic stones, from 40 to 70 grains only might be washed out (Of this method more will be said hereafter)

Further, the repeated entering and dragging out of the instruments through the whole sensitive urethra will be avoided Strictures of the urethra, so great an impediment in lithotripsy, do hardly come in question here The same is the case with prostatic troubles, which in a great part are easily removable

The instruments which render Bigelow's method so expensive become totally superfluous A much stronger built, simple lithotriptor, with a common syringe or irrigator, a scalpel and dressing forceps, are, as already stated, nearly all the instruments necessary in performing the operation And what will not finally be the benefit derived from it in a case complicated with cystitis?

In an alkaline or decomposed, putrid, purulent urine, the preparatory treatment previous to the operation ought to consist during a few days in a milk diet, rest in bed, and drinking freely of some Lithia or Bethesda water (about three or four pints daily), and some alkaline diuretics, as citrate or tartrate of potassa Repeated irrigations of the bladder of a 2½ to 3 per cent phenol water, or of a solution of borate of potassa with salicylic acid, as warm as tolerated, are besides to be applied daily Should there be a great difficulty in getting rid of the bad urine, an injection of a concentrated solution of nitrate of silver will often accomplish the desired object With regard to the after treatment, I have only to call attention to the careful searching, that no fragments are left behind Repeated irrigations of 3 per cent phenol water during day and night every fifteen minutes, may under circumstances save a life which already had been given up for lost

No instruments ought to be used if not previously well cleansed and made aseptic by placing them for half an hour in a 5 per cent phenol water, and to be greased afterwards with phenol oil (one part phenol to two parts of oil, or glycerine) Immediately after each operation, the bladder must be well irrigated with the 3 per cent phenol water

Dangerous Character of the Detritus —On several occasions I have called attention to the ill judged and absurd opinions of the action of the fragments of the crushed stone In order to present exhaustively the whole importance of that detritus and its proper understanding, inclusive treatment, I have selected here a typical case for demonstration Though I could have selected a similar case out of my own experience, I have preferred to take one from the collection of my friend, the late Professor of Surgery, of Greifswald, Prussia, Dr C Hueter We will observe the injurious process, or function, of the fragments explained in quite a different manner than usually considered where a great stress is laid upon the mechanical action of the sharp edges of the detritus

It is by the mistakes, the errors committed, that we learn how to avoid them in future, and one such case, in which we have blundered, is often more instructive and of import than a hundred others of a successful issue

The case under consideration was an inmate of the University Hospital of Greifswald, and Hueter lost his patient on the fourth day after the introduction of the lithotriptor Hueter had at first caught the calculus more in order to measure its size at that time, than intending to crush it But having caught it, as he thought, in a very favorable position for crushing, he thought to try at least the stone's hardness Experienced and expert an operator as Hueter was, by that statement he points to one of the difficulties of that operation, since not every one is a Sir Thompson, who performs the whole operation in six or seven minutes! Having satisfied himself that the calculus was not a fit one for further lithotriptic efforts he therefore concluded to perform cystotomy in a day or two later But being recalled a few hours afterwards, Hueter met the man suffering from a severe chill followed by a high fever, and a few days later the patient died under the symptoms of pneumonia The post mortem examination revealed instead of one, five oval calculi, of from 2–3 ctm in the shorter and 3–4 ctm in the larger diameter They were of a whitish color and very hard consisting of urates to the greater part, and were lying close together as eggs in a bird's nest At the fundus of the bladder was a hæmorrhagic inflammatory spot of the mucous membrane with diphtheritic streaks, covering the upper part of the folds of the mucous membrane The membrane lining also the ureters and kidneys was equally very hyperæmic Signs of a fresh pneumonia were besides visible Of the calculus, which had been caught by the instrument, a mere indentation was to be observed, and only a few small particles from the external surface of the calculus had come away Not the least injury on the mucous membrane could be detected Hueter thought that, few as the lost particles from the cortical substance of the calculus ever were, they might have been the cause of trouble, they were at least sufficient to account for the observed successive phenomena Hueter's hypothesis was "that in the formation of the calculus some *irritaments* (micro-organisms) causing inflammation, had become imbedded, which being set free by the lithotriptic effort and coming in contact with the mucous membrane, had caused a cystitis, aggravated by a diphtheritic form " This of course is but an hypothesis, yet if we admit that a catarrh may be caused by a decomposition of the urine, then also no objection can be raised against the including of some of the products of this decomposed urine into the lamellated structure of the calculus This hypothesis of the validity almost of a theory, seems to be even more reasonable than the admittance of an injurious action of such fragments, as we have here to deal with of so diminutive a character as scarcely to cause a mechanical action, notwithstanding that such is generally admitted to be the case with the detritus. That groups of micrococci, included during the formation of a calculus, may when set free, act on the mucous membrane and cause inflammation, such seems to me, as it ought to every surgeon, a more reasonable supposition than the common one of admitting mechanical injuries produced by such small fragments as were here present. The case in question besides permits scarcely of any other interpretation than the one given here, and if correct, which can hardly be doubted, it will require as an important element, an aseptic, or antiseptic treatment in every lithotriptic operation.

If such micrococci should be propagated in a high degree, a diphtheritic inflammation of the mucous membrane might be produced, which could even be transferred to the mucous tract of the urethra and the kidneys.

The pneumonia, in Hueter's case, was of course the expressed manifestation of the general diphtheritic infection of the organism. I repeat then, if in the absence of all sharp fragments, as in this case, such few trifling particles could have produced such tremendous effects, then we will have to declare our incompetence, since such small particles will almost always be retained in every such operation, though they may and fortunately do not each time cause an inflammation of such an intense character. What we may therefore learn from that important case, consists in a total change of the character of action of the fragments and in the necessity of an immediate and thorough antiseptic irrigation of the bladder after each lithotriptic act.

That in the case alluded to, in which I had for the first time introduced a lithotriptor through the whole of the urethral tract, and more for experimentation's sake to try the hardness of the calculus, that I met with a more favorable issue, I had to thank for the information I had received from Hueter's case. An immediate recourse to antiseptic phenol injections into the bladder every half hour, during one day and night, till the high fever subsided, saved my patient's life.

Hueter thought, "that he should have performed lithotomy" in his case and as early as possible, the presence of the violent cystitis to the contrary, notwithstanding.

I fully concur with this celebrated surgeon's views, with the exception, that instead of the lateral section, I would, in having performed urethro-lithotripsy, rather extend the incision in the raphe towards and into the neck of the bladder if necessary.

"The knife in such a case," says Hueter, "acts as an antipyretic, as in the incision of a septic phlegmon, or, in the resection of a putrefying joint. With an incision into the bladder not only the extraction of the calculi would have followed forthwith, and with them the removal of the cause of the diphtheritic process of the bladder, but also the removal of the inflammation itself by the antiseptic irrigation. Yet at that time the justification of performing 'lithotomy' in a patient with acute high fever and beginning pneumonia, did not exist, and many surgeons would shrink from performing it under such circumstances, even at the present day, justifiable, if not indicated as life-saving, as the operation may ever be."

It happened to Hueter's patient, what so frequently happened during the late Franco-German war, with shot wounds comprising the joints. In waiting, according to the old school, the antique customary rules for the abatement of the high fever, before undertaking the operation, it happened that the patient usually died in consequence of waiting, and the time for the operation, as a matter of course, never arrived. That during the stormy suppurative inflammation of the wounded joint an early operation, the resection of the joint, for instance, would have been indicated as life-saving. Such the old fogies neither contemplated nor comprehended. Hueter in such cases operated; he resected and saved the life of his patients, whilst the lives in the hands of the opportunists were wantonly sacrificed by the hundreds.

Here, then, is progress—progress in cystotomy on an extended urethrotomy, Mr. Erichsen's negation to the contrary, notwithstanding!

Lithotripsy no doubt has suffered during a long period from different mishaps, but even Bigelow misconstrued, in part, if not in the main, the real source of those failures, at least theoretically. If he had recognized the real character of the obnoxious fragments, it is more than doubtful that he ever would have fallen upon the construction of his costly apparatus for the sole object of the speedy removal of the detritus. Not less so is the crafty Sir H. Thompson, England's most distinguished stone cutter, caught on marshy bottom, if he still claims for lithotripsy the attribute "*the future operation for stone in the bladder*."

The rule, during the presence of a heavy catarrh of the bladder, not to undertake lithotripsy or cystotomy, on account of the danger associated with it, is therefore a maxim for serious consideration.

The oxalate and uric calculi present in a bladder, though free from a catarrhal affection, are, on account of hardness, difficult, if not impossible, to be crushed with the ordinary instruments. They will permit the operation of urethro-lithotripsy, by permitting stronger built instruments. Calculi composed of triple-phosphates, though easily crushed, are almost exclusively present in a catarrhal diseased bladder. Thus would the simple operation of lithotripsy have been narrowed down to but a few cases, if Bigelow had not, by his apparatus and the speedy and total removal of the detritus, again enlarged the lithotriptic field. But even without his costly and complicated instruments, in the presence even of a cystitis or a decomposed alkaline urine, there would not any longer exist contra indications for either crushing or cutting operations, under a thorough, methodical antiseptic irrigation of the bladder at and after each session, wherewith all and every irritation of the bladder, and danger, would cease.

With all due reverence, then, for the inventive ingenium of our gifted and skillful confreré for the construction of an apparatus so long a desideratum in the operation of lithotripsy, still, with the proper and correct recognition of the true character and nature of the mischievous consequences of the rudiments of the crushed calculus, we might nevertheless do without his apparatus and be content with most of the old instruments Such, to a certain extent, must most assuredly be a consolation to many a colleague in straightened circumstances, unable to suffer the expenses for Bigelow's litholopactic operation

In order to corroborate the correctness of what has repeatedly been stated here, I could, if needed, bring further historical proofs, not leaving the shadow of a doubt of the valuable, important and indispensable antisepsis in lithotriptic, cystotomic, urethrotomic or urethro-lithotriptic operations, no matter if under aggravated or common circumstances When a case, for instance, recovered, suffering a catarrh of the bladder and an ammoniacal fermenting putrid urine, containing pus and blood corpuscles, and in addition suffering the presence of a stone, constituting a condition where neither lithotripsy, nor cystotomy, nor any other operation could promise much to save the life of the man, but where lithotripsy had nevertheless been chosen and the man finally recovered, there is certainly reason to inquire about the adopted treatment, and that the more so, when a long series of sessions followed each other, each equally successful, and when under that treatment the urine had finally become clear and normal Need I tell it, that here only the persevering, careful methodical irrigation and washing out of the bladder after each session with an 8 per cent phenol water saved the man's life The exclusive use of these irrigations with 2 or 3 per cent phenol water and similar wet dressings accompanied with an unfailing success, may therefore be taken as a guaranty for their propriety, whatever may be said to the contrary by others Hueter, in defending equally the wet phenol dressings, was far from ignoring the importance, if not the preference, of Lister's dry protective bandage, as in general the better, still he remarks “Should chemistry give us another and less volatile material than the phenol, less interfering with the circulation and less toxic, but equally antiseptic in its effects, it might still happen that Lister's protective with all the other costly paraphernalia of his present dressings might wander into the lumber room ” To which I would like to add That such a material we have probably obtained, if not by a chemist, by at least an equally scientific man, who of late has enriched our knowledge in the field of pathology to no small extent, the distinguished discoverer of the bacillus tuberculosis and the comma bacillus of cholera, R Koch, of Berlin, Prussia And that antiseptic material is the bichloride of mercury, commonly named corrosive sublimate In a solution of one in a thousand parts of water, it destroys, after Koch's statement, every known bacterium, while in one to five thousand the propagation, even of these micro organisms, cease My experience with that per-antiseptic remedy is yet too limited of forming an opinion of its efficacy, though I have used it almost exclusively of late, retaining the phenol only for the spray, and disinfecting the instruments with a 5 per cent solution What so far I have experienced with the sublimate encourages, no doubt, to further trials

Without a proper antiseptic for the protection of wounds, or, in a cystitis with its sequelæ, the urine may become such a dangerous poisonous substance, that even a serious diphtheritic inflammation may ensue, and according to Virchow, such a diphtheritic product caused by a septic urine will act, if introduced in a skin wound of a rabbit, just as poisonous as a diphtheritic membrane taken from the fauces of a diphtheritic person

“For irrigation of the bladder and the urethral tract a 2 per cent or 3 per cent phenol solution cannot be replaced at present in regard to its efficiency,” says Hueter, “with any other known remedy ”

I will close this important chapter with another case the same author has further given us to illustrate its importance, though I believe that sufficient proofs have already been advanced to overcome every doubt which might still be harbored The case was one of lithiasis, with strictures of the urethra The urine was in such a state of decomposition as to render its stench unbearable The mucous membrane of the bladder was found covered with incrustations, its interior was rough, and in trying to remove some of those incrustations an extensive bleeding set in Hueter had witnessed the operation on two of such cases by noted surgeons, and both cases had died, one from gangrene of the bladder, a short time after the operation Hueter, in his case, performed external urethrotomy, and caused a strong current of 3 per cent phenol water to pass through the bladder and urethral opening during a quarter of an hour He applied a silver drain, a finger thick, and antiseptic wet dressings *Every three hours at day and at night, the bladder was well irrigated during a quarter of an hour each time* Not the least irritation set in, and the man's life was finally saved

I could add two more cases out of my own experience and practice In both I had performed external urethrotomy (Boutonniére) Both lives were saved under the close attention and constant antiseptic treatment Under the application of the silver drainage tube, the urethral fistules healed (one had two, the other three) This may finish the chapter of lithotripsy and urethro-lithotripsy The importance of the subject, the necessity to particularize, where so much depends upon a minute and exact performance to be successful, since not all are masters of our art, and finally, the opposition and doubts with which many of the ideas here advocated will still be considered, made it obligatory with me to particularize and support the theories with incontrovertible facts I have but one hope, and that consists in—to have succeeded

In the next chapter I intend to let the diverse methods of “the operation for stone ” pass review, but treat them, with one or two exceptions, in a more cursory manner, adding such remarks as I deem of import and of a more general interest

A CASE OF SYMPATHETIC NEURO-RETINITIS WITH CONSECUTIVE SEROUS IRITIS

BY S D RISLEY, A M , M D , ASSISTANT OPTHALMIC SURGEON HOSPITAL UNIVERSITY OF PENNSYLVANIA

Read before the Ophthalmic Section of the American Medical Association

The so-called sympathetic diseases of the eye still hold a first place in the interest of ophthalmic surgeons, not only because of their intrinsic importance, but also because of the doubt which still hangs over their pathogeny It is not my present purpose to attempt a full discussion of the important questions involved in the study of these affections of the hitherto sound eye, clinically related to pathological processes in the injured eye, but to relate briefly the history of a case which seems to call in question the correctness of the opinion which regards the consecutive affection as always of sympathetic origin

Injury to Ciliary Region Neuro Retinitis in Uninjured Eye, Consecutive Serous Iritis —John D , æt 14 Dec 26, 1882, was struck in the left eye by the arrow from a boy's gun The propelling force was a rubber band, the projectile a wooden arrow, 1 cm in diameter, 8½ cm in length, tipped with a brass ferule, from which projected a metal point 1 cm long and 3 mm in diameter, with sharpened extremity This metal extremity penetrated the eye at the corneo-sclerotic junction, in the lower and inner quadrant, making a horizontal wound nearly linear, part in ciliary region of sclera, partly in the cornea The iris was found projecting from the wound, and behind it a grape like mass, bluish-black, probably the ciliary body Ineffectual effort was made by gentle manipulation, and pressure with lower eye lid to replace the protruding mass The projecting iris was incised, leaving a nearly typical coloboma of the iris The ciliary body was then gently replaced within the wound by the horn spoon, when a button of vitreous presented in its stead Atropia was instilled, the eye bandaged and subsequently treated as after a cataract extraction The boy had suffered much shock from the injury There was violent reaction which was, however, promptly and successfully met by local depletion and aconite

The wound closed with cystoid scar, but the eye notwithstanding this rapidly lost its redness On January 22d, less than one month from the receipt of the injury, he visited the office still wearing a Liebreich bandage The following conditions were noted O S still some ciliary injection, anterior chamber normal, wound flat, no adherence of iris or ciliary body, lower and inner periphery of lens opaque, blood clot still in vitreous chamber and prevents further ophthalmoscopic study O D v = $^{20}/_{xx}$ *fac*[1] Jr , I p p 10 cm eye white and ophthalmoscope revealed a typically healthy, young eye, with H = 1, 5 D On January 31, the patient was attacked with coryza attended with slight catarrh of the conjunctiva in the right eye, for which he was treated with a slightly astringent wash The attack was attended and followed by some undue sensitiveness to light and inability to use the eye On February 3, v = $^{20}/_{xxv}$ and Jr 1 p p 17 cm Ophth shows simply undue opacity of surface of optic disk On February 13 the nerve end was as red as the surrounding choroid, and its margins blurred by the hazy retina, veins full and tortuous, no hemorrhages, media transparent, iris dilates *ad max* under atropia , conjunctival and ciliary injection remains, and there is increased lachrymation and some dread of light February 19, v had sunk to $^{20}/_{xl}$ and the ophthalmoscopic symptoms had progressed On the 26th, improvement is noted, while v is not recorded, but media are distinctly noted as transparent On March 2, only hazy view of the eye ground could be had, owing to diffuse opacity of the media, and there was seen with convex glass numerous dust-like particles in the anterior part of the vitreous body The retina was striated, circulation as before, and there were now numerous yellowish-white splotches throughout the fundus, v $^{20}/_{cxxvi}$ Examination with 2″ lens shows a few punctate opacities on membrane of Descemet in its lower half The potas iod and bromide which he had been taking steadily since the first appearance of the neuritis was continued and the mercurial bandage was prescribed in addition, with 4 gr sol of sulphate of atropia locally

Under this treatment the eye slowly but steadily improved, until on the 18th of April v rose to $^{20}/_{xx}$, ciliary injection gone and p p for Jr 1 was 15 cm , the atropia solution having been suspended for ten days On the 5th of May, it was noted eye white, corneal deposits have disappeared, no retinal haze, margins of nerve fringed, retina striated above and below the nerve, considerable absorbtion of pigment epithelium throughout the entire eye ground

On June 1, v $^{20}/_{xx}$ +, p p Jr 1, 13, cm o s v $^{20}/_{cc}$ On Apr 30, 1884, v $^{20}/_{xx}$ fac Is going to school, eyes are not troublesome In o s counts fingers with difficulty In o oph shows conus at outer side of nerve—and nerve itself grayish-green —margins fringed

The points in this case which to the reporter seem of sufficient interest to justify its publication are, first, the complete recovery of the secondarily affected eye without the removal of the injured ball, second, the insidious onset of a descending optic neuritis, followed by choroiditis, cloudy vitreous, and finally all the phenomena of serous iritis Had attention not been directed to the eye by the conjunctival catarrh attending on the coryza, it is probable that the conditions of the optic nerve and retina would have been entirely overlooked until the inflammation of the choroidal tract had so obscured the media as to prevent an accurate study of the retina and nerve

NOTE —Since the presentation of the above report the patient has had two attacks of convulsions, the first preceded by blindness The convulsions were epileptiform, attended by complete unconsciousness and followed by violent headache The first occurred in the latter part of June The patient was seen in consultation with the family physician, Dr O'Hara, of Philadelphia The ophthalmoscope re-ingenium of our gifted and skillful confreré for the construction of an apparatus so long a desideratum in the operation of lithotripsy, still, with the proper and correct recognition of the true character and nature of the mischievous consequences of the rudiments of the crushed calculus, we might nevertheless do without his apparatus and be content with most of the old instruments. Such, to a certain extent, must most assuredly be a consolation to many a colleague in straightened circumstances, unable to suffer the expenses for Bigelow's litholopactic operation.

[1] With facility

In order to corroborate the correctness of what has repeatedly been stated here, I could, if needed, bring further historical proofs, not leaving the shadow of a doubt of the valuable, important and indispensable antisepsis in lithotriptic, cystotomic, urethrotomic or urethro-lithotriptic operations, no matter if under aggravated or common circumstances. When a case, for instance, recovered, suffering a catarrh of the bladder and an ammoniacal fermenting putrid urine, containing pus and blood corpuscles, and in addition suffering the presence of a stone, constituting a condition where neither lithotripsy, nor cystotomy, nor any other operation could promise much to save the life of the man, but where lithotripsy had nevertheless been chosen and the man finally recovered, there is certainly reason to inquire about the adopted treatment, and that the more so, when a long series of sessions followed each other, each equally successful, and when under that treatment the urine had finally become clear and normal. Need I tell it, that here only the persevering, careful methodical irrigation and washing out of the bladder after each session with an 8 per cent. phenol water saved the man's life. The exclusive use of these irrigations with 2 or 3 per cent. phenol water and similar wet dressings accompanied with an unfailing success, may therefore be taken as a guaranty for their propriety, whatever may be said to the contrary by others. Hueter, in defending equally the wet phenol dressings, was far from ignoring the importance, if not the preference, of Lister's dry protective bandage, as in general the better, still he remarks "Should chemistry give us another and less volatile material than the phenol, less interfering with the circulation and less toxic, but equally antiseptic in its effects, it might still happen that Lister's protective with all the other costly paraphernalia of his present dressings might wander into the lumber room." To which I would like to add That such a material we have probably obtained, if not by a chemist, by at least an equally scientific man, who of late has enriched our knowledge in the field of pathology to no small extent, the distinguished discoverer of the bacillus tuberculosis and the comma bacillus of cholera, R. Koch, of Berlin, Prussia. And that antiseptic material is the bichloride of mercury, commonly named corrosive sublimate. In a solution of one in a thousand parts of water, it destroys, after Koch's statement, every known bacterium, while in one to five thousand the propagation, even of these micro organisms, cease. My experience with that per-antiseptic remedy is yet too limited of forming an opinion of its efficacy, though I have used it almost exclusively of late, retaining the phenol only for the spray, and disinfecting the instruments with a 5 per cent. solution. What so far I have experienced with the sublimate encourages, no doubt, to further trials.

Without a proper antiseptic for the protection of wounds, or, in a cystitis with its sequelæ, the urine may become such a dangerous poisonous substance, that even a serious diphtheritic inflammation may ensue, and according to Virchow, such a diphtheritic product caused by a septic urine will act, if introduced in a skin wound of a rabbit, just as poisonous as a diphtheritic membrane taken from the fauces of a diphtheritic person.

"For irrigation of the bladder and the urethral tract a 2 per cent. or 3 per cent. phenol solution cannot be replaced at present in regard to its efficiency," says Hueter, "with any other known remedy."

I will close this important chapter with another case the same author has further given us to illustrate its importance, though I believe that sufficient proofs have already been advanced to overcome every doubt which might still be harbored. The case was one of lithiasis, with strictures of the urethra. The urine was in such a state of decomposition as to render its stench unbearable. The mucous membrane of the bladder was found covered with incrustations, its interior was rough, and in trying to remove some of those incrustations an extensive bleeding set in. Hueter had witnessed the operation on two of such cases by noted surgeons, and both cases had died, one from gangrene of the bladder, a short time after the operation. Hueter, in his case, performed external urethrotomy, and caused a strong current of 3 per cent. phenol water to pass through the bladder and urethral opening during a quarter of an hour. He applied a silver drain, a finger thick, and antiseptic wet dressings. *Every three hours at day and at night, the bladder was well irrigated during a quarter of an hour each time.* Not the least irritation set in, and the man's life was finally saved.

I could add two more cases out of my own experience and practice. In both I had performed external urethrotomy (Boutonniére). Both lives were saved under the close attention and constant antiseptic treatment. Under the application of the silver drainage tube, the urethral fistules healed (one had two, the other three). This may finish the chapter of lithotripsy and urethro-lithotripsy. The importance of the subject, the necessity to particularize, where so much depends upon a minute and exact performance to be successful, since not all are masters of our art, and finally, the opposition and doubts with which many of the ideas here advocated will still be considered, made it obligatory with me to particularize and support the theories with incontrovertible facts. I have but one hope, and that consists in—to have succeeded.

In the next chapter I intend to let the diverse methods of "the operation for stone" pass review, but treat them, with one or two exceptions, in a more cursory manner, adding such remarks as I deem of import and of a more general interest.

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS.

THE USE OF COCAINE IN THROAT AFFECTIONS.—As an additional proof of the wonderful effects of this drug which is exciting so much attention in this country, we give a brief of the paper read by Dr. Jelinek before the Society of Physicians of Vienna, and taken from the *Wiener Medicinische Wochenschrift* by the *Medical Times*.

Dr. Jelinek first briefly reviews the various methods hitherto employed to diminish the sensibility of the pharynx and larynx, viz., the painting with sulphate of morphia, the ether spray, tannin, bromide of potassium. The use of sulphate of morphia was very commonly used. The pharynx and larynx were painted twelve times with chloroform, and after the lapse of an hour an equal number of times with a concentrated solution of morphia. This was done in the evening preceding the day of operation. The next morning the sensibility of the larynx was found so diminished that operation could be performed without distress. The disadvantages of this method were obvious. The preparation lasted twelve hours, and the patient had to be watched during the whole night, as there was a possibility of narcotism. Hydrochlorate of cocaine seemed to have been long known to French physicians, but its practical employment as an anæsthetic and anodyne had hitherto been unknown. He used dilute alcoholic solutions of ten per cent. and twenty per cent., which were at first clear, but which after some days became turbid, owing to the alcohol evaporating, and some of the cocaine being precipitated. It then became necessary to add a few drops of alcohol. Hydrochloric acid should not be used in preparing the solution, and it should not be filtered. In slight operations, where little reflex action and only moderate pain were present, the ten per cent. solution sufficed, but where the larynx had to be rendered anæsthetic for more serious operations, the twenty per cent. solution must be employed. To the pharynx the solution should be applied by means of a little mop, to the larynx by means of a thick, soft camel's hair pencil. The application must be repeated every minute and a half, if necessary. The anæsthesia lasted ordinarily from ten to fifteen minutes, and disappeared totally after twenty minutes. All those parts with which an instrument might come into contact—the margin, the lingual and laryngeal surface of the epiglottis, the palleculæ, and so on, must be painted, as reflexes might occur whenever a part had remained untouched by the solution. He then mentioned some cases in which polypi and papillomata had been removed from the larynx with considerable success. As an anodyne in cases of tuberculous perichondritis, in which delutition was so painful that the patients refused food, and were in danger of perishing from inanition, it rendered good service, the diminution of pain sometimes lasted for three hours, it was necessary to seek out all the implicated spots, and to paint them thoroughly. In these cases only aqueous solutions had been used. He further pointed out that cocaine diminished the swelling of a mucous membrane where present, lessened its secretions, and, according to Fannel, tightened the vocal cords. No local or general disturbance had been observed after its employment.

In the course of his remarks Dr. Jelinek gave one striking case somewhat in detail of a man, 45 years of age, suffering from tubercle with extensive swelling and strong infiltration of the epiglottis, but only moderate dullness and slight crepitation were discoverable at the apex of the right lung. He affirmed that for close upon two months he had only been able to swallow milk in the minutest quantities. He was extremely wasted, incapable of work, scarcely even able to walk, and tortured by continuous pain and thirst. Before applying the cocaine solution Dr. Jelinek made him drink some water. He had hardly swallowed a few drops before he started up in the greatest pain, while the water returned through his mouth and nose. Dr. Jelinek then carefully painted the lingual and part of the laryngeal surface of the epiglottis, and the palleculæ, with a ten per cent. solution of cocaine, and a minute afterwards told the patient to drink again. The man anxiously took a small mouthful, for a moment looked around in astonishment, and then, to the surprise of all, greedily swallowed the whole glassful at a single draught. On reaching home he made an excellent meal (the first he had for two months), but soon after the pain re-appeared, and three hours later was as bad as ever.

Professor V. Schrotter stated that he had succeeded in preparing patients by this method, of preparation in from three to eight days, so that they became quite indifferent to endolarnygeal manipulations.

TANNATE INJECTIONS IN CHOLERA.—Professor Cantani, of Naples, has obtained excellent results by the early treatment of cholera with enemata of warm solutions of tannic acid. (*Centralblatt fur die Medicinischen Wissenschaften. Med. Times.*) He used the solution in strength of 5 to 10 grammes of the acid to 2 m. of boiling water, with a little mucilage and laudanum. To insure success he generally made the injection as high up in the bowel as possible, but found that even with an ordinary syringe the treatment was valuable in the early stages of the disease. It was especially effective during the period of premonitory diarrhœa, which was at times completely checked even after a single injection, a period of rest following of from eight to ten hours, and further attacks being cut short in a similar way. The tannate injections seemed to prevent the excessive loss of fluid by the bowel, to permit the continuance of the flow of urine and so to stave off the typhoid state and altogether to prevent the onset of the algid period The exact mode of action of the tannic acid must remain as yet undetermined Amongst other possibilities, Professor Cantani suggests that it has a directly destructive or abortive influence upon the comma bacilli In furtherance of this view he made direct experiments upon artificially cultivated bacilli and found that, although not destroyed by the acid, the micro-organisms were checked in their reproduction and in their mobility for a period of from twenty-four to thirty six hours

Treatment of Marsh Fever by Subcutaneous Injections of Carbolic Acid —Dr Dieulafoy communicated to the *Societe Medicale des Hopitaux de Paris* (*Lancet*), the history of a patient who since 1877 had had tertian fever three times, which had always been successfully treated by the administration of quinine The fever having returned last June, the patient came under the care of Dr Dieulafoy, who on the first day injected subcutaneously two centigrammes and a half of carbolic acid, dissolved in a hundred parts of water The quantity was increased on the following day to five centigrammes, and to seven centigrammes on the days of apyrexia Recovery was complete at the end of seventeen days The patient had then absorbed eighty-four centigrammes of carbolic acid, without showing any signs of poisoning

In the subsequent discussion Dr Laveran reverted to the fact that carbolic acid injections had been employed against marsh fever so far back as 1869, with questionable success He doubted the propriety of attempting to supplant so certain a remedy as sulphate of quinine Dr Huchard related the case of an Arab, in whom quotidian attacks of fever, which had resisted all other remedies, yielded to bromide of potassium

SURGERY.

Skin Grafts from the Frog —Dr Wm Allen (*Lancet*) finds that bits of skin from a decapitated frog make grafts which admirably answer all purposes, forming a source of supply always at hand in the country, except during the winter months, being easily applied on account of their uniformity in thickness, and necessitating no pain to suffering humanity The skin of a single frog yields grafts for an enormous extent of surface and preserves its vitality so long that, if the patient is at a distance, the portion of skin required can be carried by the surgeon in his pocket for an hour or more without injury, provided it is wrapped up in gutta percha, or other water proof tissue, to prevent drying As witnessed in three cases the frog grafts at first act as human grafts are known to do, but later on their behavior is different Thus, soon after being applied they disappear, but after a short time they appear again as a thin transparent film on the surface of the granulations, some of the films being raised in the centre and depressed at the edges, forming small conical elevations At this period the skin at the edge of the wound takes on a very rapid growth, but, curiously enough, the grafts themselves grow but little, and some stop growing altogether, this being so different from what occurs in the case of human skin grafts If the wound or ulcer is a large one, the rapidity of epidermal growth at the circumference also soon diminishes, unless stimulated afresh by a second application of grafts, so that often a series of settings of grafts is needed before the granulations are closed over with skin Material for graft-making, however, being so easily procurable, the large quantity of seedlings required offers no difficulty

Dr Allen applies to this process the views of Stricker regarding the existence of sexes in the tissues The colonies of epithelial corpuscles at the edges of the ulcer remain quiescent through lack of one sexual element, which the grafts no sooner supply than reproduction rapidly sets in, fertilization being probably brought about through the medium of the fluid which bathes the surface of the granulations If the sexual theory accounts for the process, the skin that grows after the application of the frog grafts must be of the nature of a new breed, a cross between human and frog epidermal elements The disproportionate growth between the frog grafts themselves and the circumferential epithelium in no way invalidates this supposition, seeing that a somewhat analogous condition exists among animals when families of the same species are crossed with one another, fertility being greatest on the side that tends to degeneration, and less on the side that aims at a higher development

On Rhinoliths —Dr E Schmiegolow (*Nordiskt Medicinskt Arkiv*) gives the case of a rhinolith in a man 58 years of age who suffered for sixteen years from purulent and foetid discharge from the left nostril, complicated by a complete obstruction of that half of the nose For five or six years every time that he became overheated, an abundant cold sweat manifested itself over the whole of the left side of the head This phenomenon had disappeared for the last four years The left cavity of the nose was filled by a hard body which, under the shape of a fork, surrounded the inferior turbinated bone He was satisfied that he had a rhinolith to deal with, for it was not supposable that the bony tissues could furnish a sequestrum without some deformity, which did not exist The stone was removed in two sittings by means of lithotripsy It was composed of uniform layers without any nucleus, and contained but a small quantity of organic matters, among which not a trace of oxalic acid could be found The inorganic matters formed the greater part of the stone, and they consisted principally of phosphate of lime, phosphate of magnesia, carbonate of lime in small quantity, and traces of chlorides The rhinoliths are very rare, and only 20 cases are to be found in the literature of the subject What adds to the interest of rhinoliths, after their great rarity, is the difficulty in diagnosticating them A great number of these cases are treated for years as necroses of the bony tissues of vealed a fresh onset of the optic neuritis. The mercurial bandage was once more employed, and was again followed by a speedy subsidence of all the symptoms. The second attack occurred Nov. 1, 1884, was similar to the attack above described. The neuritis was once more well marked. The same treatment was once more advised, but the patient drifted into the hands of an irregular practitioner, probably in consequence of a dreaded enucleation of the injured eye.

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS.

THE USE OF COCAINE IN THROAT AFFECTIONS.—As an additional proof of the wonderful effects of this drug which is exciting so much attention in this country, we give a brief of the paper read by Dr. Jelinek before the Society of Physicians of Vienna, and taken from the *Wiener Medicinische Wochenschrift* by the *Medical Times*.

Dr. Jelinek first briefly reviews the various methods hitherto employed to diminish the sensibility of the pharynx and larynx, viz., the painting with sulphate of morphia, the ether spray, tannin, bromide of potassium. The use of sulphate of morphia was very commonly used. The pharynx and larynx were painted twelve times with chloroform, and after the lapse of an hour an equal number of times with a concentrated solution of morphia. This was done in the evening preceding the day of operation. The next morning the sensibility of the larynx was found so diminished that operation could be performed without distress. The disadvantages of this method were obvious. The preparation lasted twelve hours, and the patient had to be watched during the whole night, as there was a possibility of narcotism. Hydrochlorate of cocaine seemed to have been long known to French physicians, but its practical employment as an anæsthetic and anodyne had hitherto been unknown. He used dilute alcoholic solutions of ten per cent. and twenty per cent., which were at first clear, but which after some days became turbid, owing to the alcohol evaporating, and some of the cocaine being precipitated. It then became necessary to add a few drops of alcohol. Hydrochloric acid should not be used in preparing the solution, and it should not be filtered. In slight operations, where little reflex action and only moderate pain were present, the ten per cent. solution sufficed, but where the larynx had to be rendered anæsthetic for more serious operations, the twenty per cent. solution must be employed. To the pharynx the solution should be applied by means of a little mop, to the larynx by means of a thick, soft camel's hair pencil. The application must be repeated every minute and a half, if necessary. The anæsthesia lasted ordinarily from ten to fifteen minutes, and disappeared totally after twenty minutes. All those parts with which an instrument might come into contact—the margin, the lingual and laryngeal surface of the epiglottis, the palleculæ, and so on, must be painted, as reflexes might occur whenever a part had remained untouched by the solution. He then mentioned some cases in which polvpi and papillomata had been removed from the larynx with considerable success. As an anodvne in cases of tuberculous perichondritis, in which delutition was so painful that the patients refused food, and were in danger of perishing from inanition, it rendered good service; the diminution of pain sometimes lasted for three hours; it was necessary to seek out all the implicated spots, and to paint them thoroughly. In these cases only aqueous solutions had been used. He further pointed out that cocaine diminished the swelling of a mucous membrane where present, lessened its secretions, and, according to Fannel, tightened the vocal cords. No local or general disturbance had been observed after its employment.

In the course of his remarks Dr. Jelinek gave one striking case somewhat in detail of a man, 45 years of age, suffering from tubercle with extensive swelling and strong infiltration of the epiglottis, but only moderate dullness and slight crepitation were discoverable at the apex of the right lung. He affirmed that for close upon two months he had only been able to swallow milk in the minutest quantities. He was extremely wasted, incapable of work, scarcely even able to walk, and tortured by continuous pain and thirst. Before applying the cocaine solution Dr. Jelinek made him drink some water. He had hardly swallowed a few drops before he started up in the greatest pain, while the water returned through his mouth and nose. Dr. Jelinek then carefully painted the lingual and part of the laryngeal surface of the epiglottis, and the palleculæ, with a ten per cent. solution of cocaine, and a minute afterwards told the patient to drink again. The man anxiously took a small mouthful, for a moment looked around in astonishment, and then, to the surprise of all, greedily swallowed the whole glassful at a single draught. On reaching home he made an excellent meal (the first he had for two months), but soon after the pain re-appeared, and three hours later was as bad as ever.

Professor V. Schrotter stated that he had succeeded in preparing patients by this method, of preparation in from three to eight days, so that they became quite indifferent to endolarnygeal manipulations.

TANNATE INJECTIONS IN CHOLERA.—Professor Cantani, of Naples, has obtained excellent results by the early treatment of cholera with enemata of warm solutions of tannic acid. (*Centralblatt fur die Medicinischen Wissenschaften. Med. Times.*) He used the solution in strength of 5 to 10 grammes of the acid to 2 m. of boiling water, with a little mucilage and laudanum. To insure success he generally made the injection as high up in the bowel as possible, but found that even with an ordinary syringe the treatment was valuable in the early stages of the disease. It was especially effective during the period of premonitory diarrhœa, which was at times completely checked even after a single injection, a period of rest following of from eight to ten hours, and further attacks being cut short in a similar way. The tannate injections seemed to prevent the excessive loss of fluid by the bowel, to permit the continuance of the flow of urine and so to stave off the typhoid state and altogether to prevent the onset of the algid period The exact mode of action of the tannic acid must remain as yet undetermined Amongst other possibilities, Professor Cantani suggests that it has a directly destructive or abortive influence upon the comma bacilli In furtherance of this view he made direct experiments upon artificially cultivated bacilli and found that, although not destroyed by the acid, the micro-organisms were checked in their reproduction and in their mobility for a period of from twenty-four to thirty-six hours

Treatment of Marsh Fever by Subcutaneous Injections of Carbolic Acid —Dr Dieulafoy communicated to the *Societe Medicale des Hopitaux de Paris* (*Lancet*), the history of a patient who since 1877 had had tertian fever three times, which had always been successfully treated by the administration of quinine The fever having returned last June, the patient came under the care of Dr Dieulafoy, who on the first day injected subcutaneously two centigrammes and a half of carbolic acid, dissolved in a hundred parts of water The quantity was increased on the following day to five centigrammes, and to seven centigrammes on the days of apyrexia Recovery was complete at the end of seventeen days The patient had then absorbed eighty-four centigrammes of carbolic acid, without showing any signs of poisoning

In the subsequent discussion Dr Laveran reverted to the fact that carbolic acid injections had been employed against marsh fever so far back as 1869, with questionable success He doubted the propriety of attempting to supplant so certain a remedy as sulphate of quinine Dr Huchard related the case of an Arab, in whom quotidian attacks of fever, which had resisted all other remedies, yielded to bromide of potassium

---

SURGERY.

Skin Grafts from the Frog —Dr Wm Allen (*Lancet*) finds that bits of skin from a decapitated frog make grafts which admirably answer all purposes, forming a source of supply always at hand in the country, except during the winter months, being easily applied on account of their uniformity in thickness, and necessitating no pain to suffering humanity The skin of a single frog yields grafts for an enormous extent of surface and preserves its vitality so long that, if the patient is at a distance, the portion of skin required can be carried by the surgeon in his pocket for an hour or more without injury, provided it is wrapped up in gutta percha, or other water proof tissue, to prevent drying As witnessed in three cases the frog grafts at first act as human grafts are known to do, but later on their behavior is different Thus, soon after being applied they disappear, but after a short time they appear again as a thin transparent film on the surface of the granulations, some of the films being raised in the centre and depressed at the edges, forming small conical elevations At this period the skin at the edge of the wound takes on a very rapid growth, but, curiously enough, the grafts themselves grow but little, and some stop growing altogether, this being so different from what occurs in the case of human skin grafts If the wound or ulcer is a large one, the rapidity of epidermal growth at the circumference also soon diminishes, unless stimulated afresh by a second application of grafts, so that often a series of settings of grafts is needed before the granulations are closed over with skin Material for graft-making, however, being so easily procurable, the large quantity of seedlings required offers no difficulty

Dr Allen applies to this process the views of Stricker regarding the existence of sexes in the tissues The colonies of epithelial corpuscles at the edges of the ulcer remain quiescent through lack of one sexual element, which the grafts no sooner supply than reproduction rapidly sets in, fertilization being probably brought about through the medium of the fluid which bathes the surface of the granulations If the sexual theory accounts for the process, the skin that grows after the application of the frog grafts must be of the nature of a new breed, a cross between human and frog epidermal elements The disproportionate growth between the frog grafts themselves and the circumferential epithelium in no way invalidates this supposition, seeing that a somewhat analogous condition exists among animals when families of the same species are crossed with one another, fertility being greatest on the side that tends to degeneration, and less on the side that aims at a higher development

On Rhinoliths —Dr E Schmiegolow (*Nordiskt Medicinskt Arkio*) gives the case of a rhinolith in a man 58 years of age who suffered for sixteen years from purulent and foetid discharge from the left nostril, complicated by a complete obstruction of that half of the nose For five or six years every time that he became overheated, an abundant cold sweat manifested itself over the whole of the left side of the head This phenomenon had disappeared for the last four years The left cavity of the nose was filled by a hard body which, under the shape of a fork, surrounded the inferior turbinated bone He was satisfied that he had a rhinolith to deal with, for it was not supposable that the bony tissues could furnish a sequestrum without some deformity, which did not exist The stone was removed in two sittings by means of lithotripsy It was composed of uniform layers without any nucleus, and contained but a small quantity of organic matters, among which not a trace of oxalic acid could be found The inorganic matters formed the greater part of the stone, and they consisted principally of phosphate of lime, phosphate of magnesia, carbonate of lime in small quantity, and traces of chlorides The rhinoliths are very rare, and only 20 cases are to be found in the literature of the subject What adds to the interest of rhinoliths, after their great rarity, is the difficulty in diagnosticating them A great number of these cases are treated for years as necroses of the bony tissues of the nose, or as malignant tumors of the nasal cavity The treatment consists in their extraction as a whole or after lithotripsy If the stone is too large to be removed by a single operation, or too hard to allow of lithotripsy, it is necessary to detach the nose from its insertion to make more room

Note by the Compiler M Demarquay in 1845 published in the *Archives Générales de Méd* a case of this character where several small calculi were passed one the size of a bean on being sawn through was found to have a cherry stone for its nucleus He could only collect 14 cases to compare with his own, several of which contained cherry stones as nuclei, and in some no nucleus was found Among the symptoms, severe hemicrania was common In one case the corresponding eye became seriously affected and in another the tumor appeared to be connected with the roots of a cavious front tooth, as pulling on it caused movements of the tumor In ' A Collection of Remarkable Cases in Surgery, by Paul F Eve page 125 will be found a translation of Demarquay s article taken from the *Edinburgh Medical and Surgical Journal*, 1845

MEDICINE.

The Relation of Certain Diseases of the Eye to Gout —Mr Jonathan Hutchinson delivered the Bowman Lecture before the Ophthalmological Society of the United Kingdom, taking this subject for his text The lecture in full and a resumé of its principal points are given in the *Medical Times*

As his lecture was the first delivered, he devoted some space to insisting upon the existence of a clear distinction between gout and rheumatism, while admitting the difficulty, and even in some cases the impossibility, of actually drawing this distinction in practice By *gout* he means all states of health which are, whether directly or remotely, connected with the accumulation of lithate of soda in the blood, as the result of over-feeding or defective assimilation From the primitive idea of *rheumatism* he would exclude as causes all that have reference to food or assimilation, and would count only those which regard climate and weather, and especially exposure to cold and damp Now, the primitive type of each of these diseases becomes much modified by inheritance, *e g* , a form of transmitted gout may exist, not associated in the patient with either lithiasis or lithæmia Again, the primitive type of the one disease may be associated with an inherited form of the same disease or of the other, while an inherited form of both may co exist in the same individual The intricacy of the investigation is, therefore, manifest, and becomes almost hopelessly so when we are told that strictly rheumatic disorders, even to rheumatism itself, if it happens in the relatives of those who have had gout, lends support to the theory of family tendency to gout It is an observation confirmed by daily experience that the children of the gouty are more liable than others to attacks of rheumatic fever He gives to each hereditary diathesis the definition of arthritic susceptibility to food in the case of gout, and arthritic susceptibility to weather in the case of rheumatism There is a liability to the modification of tissues in the subject of acquired gout, and a proneness of these tissues to suffer in a peculiar manner when exposed to the ordinary exciting causes of disease The offspring of such a person inherits his tissues, and his tendencies as regards digestion, etc , and therefore has an increased proclivity to typical gout if exposed to its usual causes But, besides this, he inherits, independently of exciting causes, a liability to forms of inflammation or of degraded nutrition, which are not unequivocal gout, but which are yet the direct consequence of it in predecessors

"Hot eye" Mr Hutchinson associates with quiet or suppressed gout This affection is characterized by repeated short attacks of conjunctival congestion, and a feeling of heat and pricking in the eyeballs, and is liable to occur after taking injudicious diet In connection with this affection there also occasionally occurs sharp shooting pain in the eyeballs in persons suffering from unequivocal gout He next calls attention to a form of asthenopia, occurring in young persons, in association with inherited gout Nearly all cases of arthritic iritis are really due to gout, either alone or in association with rheumatism It is decidedly exceptional for rheumatism, pure and uncomplicated, to show any tendency to attack the tissues of the eye In considering the different types of arthritic iritis, he takes, first, the ordinary recurrent form, frequently called rheumatic iritis, which occurs in acute transitory paroxysms of well-known type A considerable number of such cases occur in the subjects of true gout, but in a much larger number of cases the concomitant symptoms are those of rheumatic arthritis and not of true gout This form of rheumatic gout is, in reality, a hybrid disease, possessing, in addition to an unquestionable share of rheumatism, an admixture also of gout tendency This view is supported by its infrequency in women, and by the age, habit of body and mode of life of those usually its subjects While iritis in association with acute or chronic rheumatism is very rare, it often accompanies the rheumatic affections induced by gonorrhœa, which occurs usually in the subjects of inherited gout He describes a true gouty iritis with cases in which is a peculiar form of destructive iritis always associated with the inheritance of a gouty constitution In favor of *relapsing cyclitis* being of a gouty origin, facts are still wanting "It is very probable that, in some cases, the constitutional cause may be gout " Little evidence can be produced in argument to show that gout does produce neuritis, but that gouty sciatica may be produced by an inflammation of the nerve or its sheath is at least plausible, and if so, it is also possible that some forms of optic neuritis may really be due to gouty inflammation. Mr Hutchinson considers that *retinitis hæmorrhagica* is very rarely seen excepting in those who are themselves gouty

He divides the different gouty eye affections into two groups, according as they are associated, with (1) acquired, or (2) inherited gout In the former group the attacks are generally acute, transitory and painful, and the patients are adults, here he places hot eye, sclerotitis, recurrent iritis and retinitis hæmorrhagica In the second group the attacks are prone to be chronic and persistent, often insidious, and usually destructive, here we find the true gouty iritis, relapsing cyclitis, and certain forms of soft cataract Indications as to treatment are afforded by the nature of the gout in the two groups

Atheroma of the Coronary Arteries —The term atheroma as applied to chronic deforming endarteritis is objectionable, since it does not fully express the condition Virchow thinks it should be limited to a fatty degeneration of the middle coat English writers largely employ the term to cover the whole process, whether the change be fatty or calcarious It is likewise so firmly implanted in the vocabulary of American medicine, that to attempt to uproot it seems hopeless, hence we conform to usage, while at the same protesting against the term Although having been observed, as a matter of great rarity, in youth and even in young children, atheroma is essentially a senile change German pathologists express themselves rather guardedly as to its etiology, aside from age and strain, while English writers, notably Bramwell, in his recent admirable work on *diseases of the heart and aorta*, look upon syphilis, gout, rheumatism, chronic alcoholism and strain as important factors in its causation Fothergill (*The Heart and its Diseases* Second edition, page 436) says "The general high blood-pressure in the arteries in the cardio-vascular changes described in the preceding chapter, is the great cause of atheromatous change in the arteries " However this may be, atheromatous change of the arteries is probably more prevalent than most practitioners realize It is said to affect most frequently the aorta and its larger branches, the arteries of the head, the coronary arteries, the splenic, and those of the extremities As a result of atheroma, the smaller vessels become inelastic and not infrequently impervious to the passage of the blood, and the consideration of this fact will enable one to appreciate how serious may be the consequences in the case of the general and coronary arteries

The anatomical character of this disease, as manifested in the nutrient arteries of the heart, and the serious changes in the cardiac muscle which result therefrom, have been forcibly described by Prof. Leyden, of Berlin, in Zeitschr f Klin Med vii , s 459-539 Such is the importance of the subject, that we give the following abstract

"The results of experimental occlusion of the coronary arteries have not been uniform, sometimes the slowing and weakening of the heart's contractions are gradual, blood pressure falls, *pari passu*, in the systematic arteries, and death occurs slowly, at other times, the cessation of the heart's action follows promptly, having been preceded by an exceedingly short interval of feeble, arythmic contractions In man the effect on the heart varies, according to the degree of the sclerosis of the coronary arteries Leyden therefore distinguishes four classes of the disease 1 That in which, although the coronary arteries are sclerotic, their function is not essentially impaired, and the nutrition of the heart is not affected, 2 There is an acute thrombic softening, or hæmorrhagic infarctus, of the heart-muscle, called by Ziegler "*myomalacia cordis*," and corresponding to *encephalo myomalacia*, the affected portions break down or undergo fatty degeneration, and thus prepare the way for an ultimate *ruptura cordis*, 3 Here are found disseminated patches of fibrous induration (*myocarditis fibrosa*), which occur chiefly in the vicinity of the apex, and, by thinning the walls of the ventricle, may occasion *aneurisma cordis*, 4 Spots of fibrous induration exist in conjunction with circumscribed areas of softened tissue, as a result of thrombi Here, evidently, the atheromatous change in the coronary arteries has not advanced steadily, but with periods of exacerbation and subsidance

According to the clinical history, one may distinguish three classes of cases 1st The course of the disease is acute, and results in sudden death After certain prodromata, such as vague anginous symptoms, dyspnœa dizziness, etc , the patient faints, is seized with a sudden, intense angina pectoris, and presenting signs of cardiac failure, such as *œdema pulmonum*, expires The autopsy reveals, aside from a possible rupture of the heart, areas of fibrous induration and recent hemorrhagic softening 2d The course of the disease in this class of cases is subacute, and is witnessed most often in men about sixty years of age. Symptoms of cardiac disturbance which may have obtained, at length increase in severity; attacks of angina become more frequent and intense, cough and dropsy augment, and finally, after weeks or months of cardiac asthma and angina, which latter, if it remits at intervals, does so only to make way for a sensation of nameless anxiety, the sufferer succumbs. The dilated heart is found to be the seat of fibrous degeneration and thinning. 3d. The progress of the disease is chronic, and is associated with advanced age. This class of cases Leyden also divides into three groups: *A*. Characterized by sudden attacks of angina; *B*. the existence of a serious cardiac lesion is revealed by shortness of breath, feeble pulse, inability to exertion, etc., which may exist for five, ten, or fifteen years, but physical signs other than a weak, irregular action of the heart are wanting; the compensation is evidently good. *C*. The compensation has been destroyed; orthopnœa and œdema are developed, and the heart fails in an attack of more than usually acute angina, or death approaches slowly, ushered in by signs and symptoms of venous congestion. The post-mortem appearances are essentially the same as already described.

Finally, Leyden is of the opinion that angina pectoris most frequently accompanies lesion of the heart-muscle, due to atheroma of the coronary arteries.

SCIENTIFIC ITEMS OBTAINABLE FROM THE CREMATORIES.—General acquiescence in the process of cremation seems to be steadily growing among the people, if we may judge from the establishment of crematories. Some time ago an announcement was made from the Le Moyne Crematory that it would for the future be reserved for the service of the county in which it is built. We learn from the *Medical Record* that one is in process of erection in New York, one in New Orleans, one has been talked of in Chicago, and the *British Medical Journal* informs us that in the city of Edinburgh one has just been opened, whilst one is already in operation at Woking, one of the general burying places of London.

We trust that some of our scientifically disposed men may seize the opportunity thus afforded of so arranging the process of cremation that it may yield valuable facts to the science of medicine. The estimation of the amount of "ash" obtainable from the human body, or from any animal organism, as far as we are aware, has never been ascertained on a large scale, but by a judicious arrangement at the foundation of any crematory an extensive series of observations could be instituted which could not, under any other circumstances, be made. There will necessarily be kept, at the office of every such building, a record of age, name, sex, cause of death, etc., of every body cremated, and it would only be necessary to add the question of weight, the general condition of the body, and a few other items, to furnish a record of great interest in a scientific point of view. In order to do this satisfactorily, however, it will be necessary to institute, from the commencement, the practice of cremating the body in a shroud of definite quality, so that the ash resulting from the garments may interfere as little as possible with the definite amount of ash coming from the body itself. To this observance, by a very slight manœuvre, the public could readily be educated. The ash from the body alone would be to them more sacred than the same mixed with the residue from the garments.

Whilst the crematories could furnish facts relative to the ash resulting from the body as a whole, we are satisfied that the pathologist would do well to turn his attention to the incineration of definite weights of definite organs in various pathological conditions.

It is quite possible, even, that a series of observations in this respect may throw some light on the question of tuberculosis. Even if it merely revealed to us that a given weight of a tuberculous lung yielded only the same weight of ash as a normal lung, the fact would be worth recording. For this purpose it is a question whether fragments of many of the interesting specimens in many of our museums which have been preserved in simple alcohol could not with profit be incinerated, and the resulting information be appended to the record of the specimen. At any rate the chemical incombustible constituents of diseased organs could, we think, with profit be ascertained, with the hope that it would throw some light on the more complex question of morphology.

It is not necessary to say that valuable information may be obtained from the ash of such subjects as had been treated for a prolonged period with iron, mercury or arsenic. It may even happen that, by some extra care, the process of incineration may be the the most efficient means of detecting poisoning by the last mentioned substance. Of course we do not forget that, without some precaution, the salts of arsenic and mercury would be volatilized, but whilst they are volatilized they must also, at a reduced temperature, be again deposited, and it remains for the chemist to determine the most efficient contrivance for recognizing its deposition.

CHOLERA AND PERSONAL HABITS.—The letter from our regular correspondent in Paris, in the JOURNAL of last week, was chiefly occupied with an account of the recent prevalence of epidemic cholera in that city, the writer selecting his facts principally from official reports and the discussions in the medical societies. This week we give another letter on the same subject, from an occasional correspondent who derived his information more from personal observations and inquiries during a temporary stay in Paris while the disease was in progress. Both correspondents represent the disease as commencing among the poorest and most unsanitary part of the population, the "rag pickers," and in the quarters occupied by them. Both emphasize the statement that those who were addicted to habits of dissipation and personal uncleanliness furnished by far the larger proportion of those who fell victims to the disease. And another writer states that of those admitted to the hospitals, at least 60 per cent., were known to be addicted to the habit of *drinking*.

The same general fact has been observed regarding every cholera epidemic of which we have a history. And yet, while our sanitarians and State Boards of Health have very properly issued circulars, urging upon the attention of municipal authorities and the people generally the necessity of strict cleanliness and ventilation of sewers, streets, houses, etc., as measures of prevention, comparatively slight allusions have been made to the equally important prophylactic effect of personal habits of temperance and virtuous living. We do not speak hastily when we express the opinion that indulgence in the use of fermented and distilled drinks with the personal irregularities of life occasioned thereby, have in past epidemics of cholera determined more attacks of the disease than uncleanly streets, bad sewerage, and imperfect house ventilation combined. In saying this we do not desire to detract in the least degree from the importance of giving the strictest attention to the latter by municipalities and health authorities everywhere. But more efficient means should be employed to impress the fact upon the minds of all classes of people, that attacks of epidemic cholera are directly invited by personal excesses and habits of intemperance! Such habits not only invite attacks, but they greatly increase the tendency to fatal results when attacks do occur.

AN INTERNATIONAL SANITARY CONFERENCE.—In an editorial in the *British Medical Journal* of Dec. 20, 1884, allusions are made to the international sanitary conferences on the subject of preventing the spread of epidemic cholera, held first in Constantinople in 1866, and second at Vienna in 1874, and another conference is suggested at the present time as likely to be productive of much good. At the conference of 1874 the efficacy of both maratime and land quarantine was denied, and only a limited amount of the former, coupled with inspection and detention of the sick, was deemed admissible. The establishment of an International Sanitary Commission, for practically enforcing the policy agreed upon, was then proposed, but never carried into effect. Since that time England has strictly adhered to the principles adopted at the Congress of 1874, only perfecting its practical details, while the continental nations, on the first appearance of cholera in Egypt, rushed back to all the cruelties and absurdities of both maratime and land quarantines, aided by sanitary cordons of the most absolute character. And yet while England has been unsparingly denounced, not only on the continent of Europe, but by some in our own country, as wantonly risking the safety of all Europe by adhering to her well-considered system of inspection and detention of the sick, we see the cholera, in its own good time, commence at Toulon and march steadily on, not by way of Liverpool or London, but directly through France, Italy, and some parts of Spain until it meets the cold weather of autumn in the more unsanitary streets of Paris. The suggestion of the *British Journal*, in favor of another International Conference at an early day, is a good one.

DEATH OF DR. HENRY A. MARTIN, OF BOSTON.—We have just received an interesting obituary notice of Dr. Martin, so long well known in connection with the cultivation and supply of vaccine virus, and who died on the 7th ult. We shall find room for the obituary in our present issue.

SOCIETY PROCEEDINGS.

CHICAGO MEDICAL SOCIETY.—MEETINGS FOR DEC. 1 AND 15, 1884.

We were furnished with full reports of these meetings by the secretary, but the columns of the JOURNAL were so occupied that we had no space for them, and hence give the following abstract.

At the meeting of December 1, Dr. Robert Tilley presented the case of a boy, aged 6 years, who had received a very extensive lacerated wound of the scalp and face, but which, by a careful exercise of surgical skill, had been so repaired as to leave comparatively little deformity.

Dr. W. W. Jaggard read an interesting paper on "Palliative Measures in Ruptured Extra-Uterine

Pregnancy," which has already appeared in full in the columns of the JOURNAL

Dr D A K Steele reported, in detail, three cases of ovariotomy, *one of which was followed by death*, the other two recovered The fatal result in the first case was determined by peritonitis, apparently the result of a sponge accidentally left in the lower part of the peritoneal cavity, as proved by a post-mortem examination The other two cases were accompanied by no unusual symptoms or modes of procedure, and made good recoveries

Dr C T Parks reported three cases of laparotomy, two for the removal of ovarian cysts, both terminating in recovery of the patients The third was for the removal of a supposed fibroid tumor of the uterus in a woman who had never borne children The tumor occupied closely the entire cavity of the pelvis, causing much difficulty in defecation and urination, and was firmly fixed in its position An incision through the abdominal walls was first made sufficient to ascertain that the tumor was not attached to the intestines The incision was then enlarged and an effort made to lift the mass of morbid growth so as to remove it entire, either with or without the uterus and its appendages This was finally done by the aid of an assistant pressing upward through the vagina, and the entire mass, with the uterus, was drawn through the abdominal incision A sufficient amount of the cervix was found unaffected to constitute a good pedicle for the ligature A solid rubber cord was passed around the narrowest part, and drawn as tight as possible The diseased mass was then cut away half an inch above the ligature While the surgeon turned to lay the diseased mass on the table, the rubber cord rolled over the free end of the stump, and the latter fell back into the pelvis, and a torrent of blood flowed from the severed vessels It was immediately seized between the thumb and fingers and again drawn through the abdominal incision when the bleeding stopped The pedicle was then transfixed and tied in halves with strong silk ligatures After cleansing carefully the pelvic and abdominal cavities, the pedicle was dropped back to its place, the intestines, which had been forced out during the operation, in spite of the most careful efforts of assistants to prevent, were returned carefully, and the abdominal wound closed The whole operation occupied nearly two hours, but the patient was placed in bed with only moderate symptoms of shock, and in six hours reaction was well established, and the patient had some sleep This was followed by persistent vomiting for twelve hours, when it ceased for about the same length of time, and the pulse and the temperature were favorable The vomiting then recurred and continued until the death of the patient, forty hours after the operation A superficial post mortem examination, which was all that could be obtained, showed no hemorrhage, only slight effusion into the peritoneal cavity, but about six inches in length of the ilium in a state of complete gangrene No twist or strangulation of the intestines was found to explain the occurrence of the gangrene

The cases reported by Drs Steele and Parks, elicited remarks by Drs Tilley, Angear, Etheridge, Bogue, and others, and at a late hour the society adjourned

At the meeting of December 15, Dr J B Murphy reported two cases coming under his observation of what he regarded as Actinomycosis The first was in the person of a young woman, the other in a young man In both the fungus commenced its work around the neck of a tooth, giving rise to alveolar abscess, in the pus from which the fungi were shown by the microscope Both cases recovered, the first speedily after the extraction of the tooth, but the other continued until an abscess formed behind the angle of the jaw and another in the neck The diagnosis of Dr Murphy was confirmed by Dr C Fenger, but its correctness was doubted by Dr Tilley and others The discussion and microscopic examinations occupied the whole evening

STATE MEDICINE

REPORT OF PROCEEDINGS OF THE ILLINOIS AND WEST VIRGINIA STATE BOARDS OF HEALTH.

While the various subjects embraced under the head of "State Medicine" have, within the last few years, received more attention from physicians than during former years, there is still much need of awakened enthusiasm relative thereto among the toiling thousands of the profession, while, as to the citizens in general, the work of enlightenment upon such subjects has just commenced Here, as elsewhere, the "*harvest is ripe, but the laborers are few*"

It might be expected that every physician, at least, should be an active, working sanitarian, but, as yet, "curative" medicine has its engrossing duties, and either time is wanting or pecuniary necessity is such as to prevent a large portion of the hard workers from giving more than a passing glance at the subject mentioned

Of all the different departments of "State Medicine" it is no doubt true that "Public Hygiene" is the one that should be most persistently taught the people in general Many other departments may be regulated, or practically carried out by the efforts of the few But without the coöperation of an intelligent public, the individual members of which have been brought to see the need of the precautions or active efforts that sanitarians can so well portray, we cannot hope for more than a minimum of practical good results

But how shall they be taught without a teacher? We have a few teachers to be found in Boards of Health, Sanitary Societies, and as individual sanitarians, but as yet, such teachers are too closely confined within narrow limits

Among the best text-books for the dissemination of sanitary knowledge, are the reports of the various State and local Boards of Health, but such reports seldom reach others than those already imbued with the true principles of sanitation The *facts* contained in such reports should be brought before the entire medical profession, and, indeed, before each citizen

We have before us the Fifth Annual Report of the Illinois State Board of Health, and the Third Annual Report of the West Virginia State Board

The Boards of Health, both of Illinois and West Virginia, act as Examining Boards to determine the qualifications of those entering the practice of medicine and surgery, thus supervising two departments of "State Medicine" While we may differ from others as to the policy of delegating both duties to one Board, we cannot but acknowledge that the work of the Illinois State Board of Health, for the last seven years, has achieved such good results that adverse criticism is not to be thought of, while the West Virginia Board, judging by the sample work since its organization, gives promise of advance, both as regards Public Hygiene, and the elevation of the interests of "Curative Medicine"

The last report of the Illinois Board is more voluminous than any of its predecessors A work of over six hundred pages, and within it meat enough to sustain many workers in the cause, and enough of light to illumine a greater radius than heretofore We shall only speak of its contribution to public hygiene, leaving detailed statements of the work as an "examining board" to others, or to a future time

In the history of the epidemic of small-pox (1880–82) we find the following statement "During the year 1881 there were seventy-nine different outbreaks reported outside of Chicago, causing an aggregate of seven hundred and seventy-four cases, with one hundred and seventy deaths, and in all but six of these outbreaks the origin was directly traced to newly arrived immigrants or to intercourse with places infected by immigrants"

In January the secretary reported to Dr Smith, of the National Board, that "by the observance and enforcement of the instructions of the State Board there were not, at the outside, five hundred cases of small pox and varioloid in a population of three hundred thousand souls"

Such "instructions and regulations" by which this result was accomplished was the vaccination of school children and adults, with bovine virus mainly, by competent physicians, who were obliged to certify to the result of their work, and not merely that they had performed the operation He states that "the efforts of the board met with but little opposition from the people" All this corresponds with the course of events and facts that occurred under our own observation and by our direction in Indiana during the same period

This is the "key-note" of the whole matter relative to the prevention of small-pox We need not notice further Divinity, through its "instruments," has given us knowledge of the means by which small-pox can be prevented, and yet as there are thousands who fight Divinity, we cannot be surprised that numbers of the same class, ignorant or depraved, fight the good things He sends, even though they perish themselves It is not proper that sanitarians should either skulk behind barriers or raise the white flag to avoid the onslaught of such natures A steady, vigorous, onward course is called for

While the scientists, physicians, and sanitarians are searching for the cause of diseases, with a view of more effectually preventing them, and while means are being sought to prevent other diseases upon the same plan as is known to be effectual in small-pox, it appears absurd for any one to raise opposition to the most stringent enforcement of vaccination of children and adults (both native and immigrant) until all have been successfully vaccinated, and then to continue such work with children If this were done all tentative measures would be useless Isolation, quarantine, disinfection (for this special disease) would all be things of the past We can simply say, that among the army of workers in this special department of "public hygiene," that Dr Rauch, aided and supported by his board, has accomplished much by his bold, energetic, and persistent efforts, and this mainly by impressing the truth upon the minds of others, causing responsive action

Dr Rauch, the secretary of the Illinois State Board has, as is well known by sanitarians, paid particular attention to the part taken by immigrants in the introduction and spread of small-pox in the United States and Canada, and he advances the following proposition as having been demonstrated by the operations of the Immigrant Inspection Service of the National Board of Health

1 The immigrant is a prime factor in the origin and continuation of small-pox in the United States, on the one hand, even if protected himself, often being the bearer of the contagion in clothing and other effects, and on the other, if unprotected, frequently becoming the victim to the disease and propagating it to others

2 Local efforts and expedients, either by States or municipalities, are inadequate to the control of small-pox in any given community or commonwealth so long as the contagion and material for the propagation of the contagion, continue to be replenished by repeated accessions of unprotected or improperly protected immigrants

3 "A cautious sanitary surveillance of immigrant travel from the port of arrival to the point of ultimate destination, such surveillance to consist of repeated inspection, vaccination of all unprotected, systematic observation of suspicious sickness, prompt removal and isolation of small-pox or other contagious cases, disinfection of baggage, clothing, cars, etc, is essential to supplement whatever preventive measures can be secured before embarkation, during the voyage or at the port of arrival"

These propositions are considered separately, and proven to be true They contain both the object that has inspired the actions of the Board and its able secretary, and also the result of such action

The secretary gives a detailed statement as to vaccination of school children The order for the prosecution of such work being issued December 1, 1881, and also supplement orders of January 21, 1882, January 23, 1882, and September 20, 1882 At the time of issuing the first order there were 713,431

Pregnancy," which has already appeared in full in the columns of the JOURNAL

Dr D A K Steele reported, in detail, three cases of ovariotomy, one of which was followed by death, the other two recovered The fatal result in the first case was determined by peritonitis, apparently the result of a sponge accidentally left in the lower part of the peritoneal cavity, as proved by a post-mortem examination The other two cases were accompanied by no unusual symptoms or modes of procedure, and made good recoveries

Dr C T Parks reported three cases of laparotomy, two for the removal of ovarian cysts, both terminating in recovery of the patients The third was for the removal of a supposed fibroid tumor of the uterus in a woman who had never borne children The tumor occupied closely the entire cavity of the pelvis, causing much difficulty in defecation and urination, and was firmly fixed in its position An incision through the abdominal walls was first made sufficient to ascertain that the tumor was not attached to the intestines The incision was then enlarged and an effort made to lift the mass of morbid growth so as to remove it entire, either with or without the uterus and its appendages This was finally done by the aid of an assistant pressing upward through the vagina, and the entire mass, with the uterus, was drawn through the abdominal incision A sufficient amount of the cervix was found unaffected to constitute a good pedicle for the ligature A solid rubber cord was passed around the narrowest part, and drawn as tight as possible The diseased mass was then cut away half an inch above the ligature While the surgeon turned to lay the diseased mass on the table, the rubber cord rolled over the free end of the stump, and the latter fell back into the pelvis, and a torrent of blood flowed from the severed vessels It was immediately seized between the thumb and fingers and again drawn through the abdominal incision when the bleeding stopped The pedicle was then transfixed and tied in halves with strong silk ligatures After cleansing carefully the pelvic and abdominal cavities, the pedicle was dropped back to its place, the intestines, which had been forced out during the operation, in spite of the most careful efforts of assistants to prevent, were returned carefully, and the abdominal wound closed The whole operation occupied nearly two hours, but the patient was placed in bed with only moderate symptoms of shock, and in six hours reaction was well established, and the patient had some sleep This was followed by persistent vomiting for twelve hours, when it ceased for about the same length of time, and the pulse and the temperature were favorable The vomiting then recurred and continued until the death of the patient, forty hours after the operation A superficial post mortem examination, which was all that could be obtained, showed no hemorrhage, only slight effusion into the peritoneal cavity, but about six inches in length of the ilium in a state of complete gangrene No twist or strangulation of the intestines was found to explain the occurrence of the gangrene

The cases reported by Drs Steele and Parks, elicited remarks by Drs Tilley, Angear, Etheridge, Bogue, and others, and at a late hour the society adjourned

At the meeting of December 15, Dr J B Murphy reported two cases coming under his observation of what he regarded as Actinomycosis The first was in the person of a young woman, the other in a young man In both the fungus commenced its work around the neck of a tooth, giving rise to alveolar abscess, in the pus from which the fungi were shown by the microscope Both cases recovered, the first speedily after the extraction of the tooth, but the other continued until an abscess formed behind the angle of the jaw and another in the neck The diagnosis of Dr Murphy was confirmed by Dr C Fenger, but its correctness was doubted by Dr Tilley and others The discussion and microscopic examinations occupied the whole evening

STATE MEDICINE

REPORT OF PROCEEDINGS OF THE ILLINOIS AND WEST VIRGINIA STATE BOARDS OF HEALTH.

While the various subjects embraced under the head of "State Medicine" have, within the last few years, received more attention from physicians than during former years, there is still much need of awakened enthusiasm relative thereto among the toiling thousands of the profession, while, as to the citizens in general, the work of enlightenment upon such subjects has just commenced Here, as elsewhere, the "harvest is ripe, but the laborers are few"

It might be expected that every physician, at least, should be an active, working sanitarian, but, as yet, "curative" medicine has its engrossing duties, and either time is wanting or pecuniary necessity is such as to prevent a large portion of the hard workers from giving more than a passing glance at the subject mentioned

Of all the different departments of "State Medicine" it is no doubt true that "Public Hygiene" is the one that should be most persistently taught the people in general Many other departments may be regulated, or practically carried out by the efforts of the few But without the coöperation of an intelligent public, the individual members of which have been brought to see the need of the precautions or active efforts that sanitarians can so well portray, we cannot hope for more than a minimum of practical good results

But how shall they be taught without a teacher? We have a few teachers to be found in Boards of Health, Sanitary Societies, and as individual sanitarians, but as yet, such teachers are too closely confined within narrow limits

Among the best text-books for the dissemination of sanitary knowledge, are the reports of the various State and local Boards of Health, but such reports seldom reach others than those already imbued with the true principles of sanitation The *facts* contained in such reports should be brought before the entire medical profession, and, indeed, before each citizen

We have before us the Fifth Annual Report of the Illinois State Board of Health, and the Third Annual Report of the West Virginia State Board

The Boards of Health, both of Illinois and West Virginia, act as Examining Boards to determine the qualifications of those entering the practice of medicine and surgery, thus supervising two departments of "State Medicine" While we may differ from others as to the policy of delegating both duties to one Board, we cannot but acknowledge that the work of the Illinois State Board of Health, for the last seven years, has achieved such good results that adverse criticism is not to be thought of, while the West Virginia Board, judging by the sample work since its organization, gives promise of advance, both as regards Public Hygiene, and the elevation of the interests of "Curative Medicine"

The last report of the Illinois Board is more voluminous than any of its predecessors A work of over six hundred pages, and within it meat enough to sustain many workers in the cause, and enough of light to illumine a greater radius than heretofore We shall only speak of its contribution to public hygiene, leaving detailed statements of the work as an "examining board" to others, or to a future time

In the history of the epidemic of small-pox (1880–82) we find the following statement "During the year 1881 there were seventy-nine different outbreaks reported outside of Chicago, causing an aggregate of seven hundred and seventy-four cases, with one hundred and seventy deaths, and in all but six of these outbreaks the origin was directly traced to newly arrived immigrants or to intercourse with places infected by immigrants"

In January the secretary reported to Dr Smith, of the National Board, that "by the observance and enforcement of the instructions of the State Board there were not, at the outside, five hundred cases of small-pox and varioloid in a population of three hundred thousand souls"

Such "instructions and regulations" by which this result was accomplished was the vaccination of school children and adults, with bovine virus mainly, by competent physicians, who were obliged to certify to the result of their work, and not merely that they had performed the operation He states that "the efforts of the board met with but little opposition from the people" All this corresponds with the course of events and facts that occurred under our own observation and by our direction in Indiana during the same period

This is the "key-note" of the whole matter relative to the prevention of small-pox We need not notice further Divinity, through its "instruments," has given us knowledge of the means by which small-pox can be prevented, and yet as there are thousands who fight Divinity, we cannot be surprised that numbers of the same class, ignorant or depraved, fight the good things He sends, even though they perish themselves It is not proper that sanitarians should either skulk behind barriers or raise the white flag to avoid the onslaught of such natures A steady, vigorous, onward course is called for

While the scientists, physicians, and sanitarians are searching for the cause of diseases, with a view of more effectually preventing them, and while means are being sought to prevent other diseases upon the same plan as is known to be effectual in small pox, it appears absurd for any one to raise opposition to the most stringent enforcement of vaccination of children and adults (both native and immigrant) until all have been successfully vaccinated and then to continue such work with children If this were done all tentative measures would be useless Isolation, quarantine, disinfection (for this special disease) would all be things of the past We can simply say, that among the army of workers in this special department of "public hygiene," that Dr Rauch, aided and supported by his board, has accomplished much by his bold, energetic, and persistent efforts, and this mainly by impressing the truth upon the minds of others, causing responsive action

Dr Rauch, the secretary of the Illinois State Board has, as is well known by sanitarians, paid particular attention to the part taken by immigrants in the introduction and spread of small-pox in the United States and Canada, and he advances the following proposition as having been demonstrated by the operations of the Immigrant Inspection Service of the National Board of Health

1 The immigrant is a prime factor in the origin and continuation of small-pox in the United States, on the one hand, even if protected himself, often being the bearer of the contagion in clothing and other effects, and on the other, if unprotected, frequently becoming the victim to the disease and propagating it to others

2 Local efforts and expedients, either by States or municipalities, are inadequate to the control of small-pox in any given community or commonwealth so long as the contagion and material for the propagation of the contagion, continue to be replenished by repeated accessions of unprotected or improperly protected immigrants

3 "A cautious sanitary surveillance of immigrant travel from the port of arrival to the point of ultimate destination, such surveillance to consist of repeated inspection, vaccination of all unprotected, systematic observation of suspicious sickness, prompt removal and isolation of small-pox or other contagious cases, disinfection of baggage, clothing, cars, etc , is essential to supplement whatever preventive measures can be secured before embarkation, during the voyage or at the port of arrival"

These propositions are considered separately, and proven to be true They contain both the object that has inspired the actions of the Board and its able secretary, and also the result of such action

The secretary gives a detailed statement as to vaccination of school children The order for the prosecution of such work being issued December 1, 1881, and also supplement orders of January 21, 1882, January 23, 1882, and September 20, 1882 At the time of issuing the first order there were 713,431 enrolled scholars in the State, less than one-half had been vaccinated, within sixty days nearly ninety-three per cent of them in attendance had presented evidence of being successfully vaccinated, an increase from four hundred and fifty to nine hundred and forty of all school children vaccinated

The secretary estimates that the recent small pox epidemic cost the State a round total of nearly a half-million dollars, but if estimate is made upon the value of the time consumed in sickness, the diminished productive power and the expense of supporting the disabled survivors, and including the money value of lives lost, the amount would be swelled to a grand total of over fifteen million dollars But we can do no more than to commend the utterances relative to small-pox and its prevention that are found in this report for the study of every one interested in having the fatal disease stamped out

Such a work as has been accomplished in Illinois, cannot, we think, have been excelled in any other State, and this owing largely to the liberal ideas of the secretary and Board of Health, as to what was needed, and the energy with which it was prosecuted There was neither hot headedness nor hesitancy The opposing forces appear to have been met and handled with fearless tact

The Board of West Virginia cannot show by its reports the same *amount* of work accomplished as that of the Illinois Board, as it was only established in 1881, the act creating it being adopted March 8, 1881, the same year and month that the act creating the State Board of Indiana was enacted, but we can not criticise the *quality* of the work as shown by this report Like the Illinois law, that of West Virginia empowers the Health Board to act also as a board to determine the qualification of those engaging in the practice of medicine, and otherwise to "regulate the practice"

THE REPORT OF THE SECRETARY TO THE GOVERNOR OF THE STATE

Gives the proceedings of the several meetings of the Board, copies of circulars issued, of blanks for certificates of qualifications of physicians, etc The work of the Board does not embrace the collection of vital statistics, and in viewing the financial statement this fact must be kept in mind We find that the total receipts from special tax, fees, etc, from June 13, 1881, to August 10, 1883, were $1,745, total disbursements, $3,241 51 The excess of disbursements over receipts ($1,496 51) was paid by the State The salary of the secretary was $500 per annum Certainly all these figures show that the work in West Virginia has been hampered by want of funds, this, however, is the case in nearly all States where similar work has been organized It is also a fact that secretaries of boards of health, as a rule, must act because of personal interest in the welfare of the work, certainly not because of the money returns

Both Dr Rauch and Dr Reeves are men who have worked the matter from the ground up, but through all their labors have been somewhat more fortunate than others in escaping trouble in shape of onslaught from professional enemies or political aspirants THAD M STEVENS, M D

Indianapolis, Indiana

FOREIGN CORRESPONDENCE

LETTER FROM PARIS—THE CHOLERA EPIDEMIC

FROM AN OCCASIONAL CORRESPONDENT

PARIS, Nov 22, 1884

MR EDITOR —Believing that a short account of the recent epidemic of cholera which has visited this city may be of interest to some readers of the JOURNAL, I send you a brief description of what it came in my way to observe

I reached Paris, Oct 20 In Berlin the weather had been cold with frequent drizzling rains and a dull, dark and dismal atmosphere I was told that a somewhat similar state of things had also been present in Paris, although the weather was fine on my arrival During the four weeks of my stay in this city, there have been two rainy and two or three cloudy days The weather during the remaining time has been generally clear, and the temperature cool, the midday averaging perhaps 50° F to 55° F

The drainage of the greater part of the city seems to me excellent The sewers are supplied with an abundance of water from the public fountains and other sources, and the mains are regularly opened in the streets or beneath the sidewalks for the purpose of additional flushing I have not been able to detect any odor from the sewer openings and in the houses where I have been there was not the slightest perceptible trace of sewer gas

I did not go through the sewers, but a friend who travelled some five miles through main or contributary sewers on Oct 25, described the condition of the sewerage as very dilute, and except in a few localities at the junction of trunk sewers there was no offensive odor The telegraph system of Paris is also conveyed in the interior of the sewers, and one of the men constantly employed in repairs and new construction said that he had not been sick or in any way unpleasantly affected by the work in the sewers during five years of service

In some limited districts of Paris, the improved sewerage system has never been fully carried out, and one may there see still the old form of gutter near the sidewalk, with more or less offensive and discolored contents The older houses are also built in the shape of a square block inclosing a small court-yard where the water supply for the entire building is located, and the drainage, except from the latrines, flows through the court-yard and under the main entrance to the street in an uncovered gutter Here there may at times be noticed a somewhat offensive odor

The food supply seems to be exceptionally good I visited the great central market "les Halles" at one o'clock in the morning I could observe nothing in the least degree questionable in quality and was struck by the absence of "second class" articles of food consumption There is evidence of a vigorous inspection of articles of food supply

The water is of surface origin and is soft in quality, clear in appearance and free from perceptible odor or taste I believe the house service is generally by a supply tank and not by direct flow from the mains

I have no knowledge of the milk supply further than the fact that in several places of pleasure resort there are stables in which cows are kept and visitors enter the stalls and for a small price receive a cup of milk warm from the cow I tasted no milk which impressed me as bad, and saw no dirty milk

Under these conditions cholera appeared in the city, and after four or five days had assumed such proportions in the form of an epidemic that it was impossible to further conceal the fact of its existence

The first cases occurred in one of the poorest districts in the city and were for a time confined to certain large tenement houses, inhabited by rag-pickers and occupied in part as a depository or depôt for rags of all kinds The first patients were without an exception those of intemperate and filthy habits, who were badly housed, insufficiently nourished, poorly clad and much exposed to cold and wet Many of the earlier cases died without treatment or were treated at their homes, but soon arrangements were adopted for the immediate transportation of cholera patients to the various hospitals, where special isolated wards were devoted to their care Removal from the patient's home was never made obligatory, nor was it considered necessary to place the infected houses in quarantine or to establish police supervision over the residents At this time no restrictions were placed on travel between Paris and the southern parts of France

For some days after the official announcement of the existence of an epidemic the disease increased in severity and extended from its point of first appearance to nearly every ward of the city In nearly all instances some means of infection from previous cases could be traced, but in some cases it was not possible to discover the manner by which the disease had been acquired

A volunteer medical service was at once established, and with the cooperation of the municipal sanitary board and the aid of the police, the city was thoroughly patrolled and every offensive place either cleansed by the authorities or by the owners or occupants of the property The smell of disinfectants was frequently noticeable, and the public streets and squares were, if possible, kept even more scrupulously clean than before In many streets the gutters were constantly flushed by opening the hydrants, and the public urinals were disinfected Each day the Mayor issued an official bulletin in which the number of cases under treatment and the number of new cases was announced, as well as the rate of dissemination of the disease by wards in the city It was stated that the highest rate only amounted to one patient to 17,000 inhabitants The cases were usually of a mild type, the mortality never, to my knowledge, exceeded 33 per cent of the number of patients, and except in an outbreak which occurred in an asylum for the aged supported by the scanty means of a few sisters of a religious order, there was no appearance of especial virulency about the epidemic In this asylum the inmates who took the disease were, I believe, all above 70 years of age, and the mortality, as might have been expected, was relatively very high Here also occurred the only instance of the entire epidemic in which a nurse or attendant was known to take the disease One of the sisters, who was constantly in the room devoted to cases of cholera, is said to have taken the disease and, after two days, died from it

As may be supposed, many persons then in Paris were much alarmed by the presence of cholera, as well as by the apprehension that neighboring cities might establish quarantine against persons or commerce from French ports, and a general exodus of travellers and strangers at once took place

It is estimated that within four days more than 30,000 people crossed the channel to various ports in England, nearly all of whom came from Paris The hotels became literally empty Many families who were established for the winter at once left the city, and a vast change was immediately noticeable in the clubs, thoroughfares, and fashionable restaurants Strange to say, the resident inhabitants of Paris did not become in the least frightened No signs of a panic were at any time observable The theatres were better filled during the first week of cholera than during the previous week, and no change was noticeable in the behavior of the common people, that element which is generally most easily frightened by any unusual occurrence

After about ten days of maximum severity the number of cases and the gravity of the disease became gradually diminished, until to day the epidemic is at an end Cases of so-called "choleraic" disease were reported for some days after the subsidence of true cholera, but these were uniformly of mild character, and ended in every instance by recovery

The reports of cases in the military establishments are very unsatisfactory, and are not taken into account, though there were doubtless a few cases in the barracks

The reported treatment consisted in a general way in the moderate use of anodynes, the administration of stimulants, the application of external heat, and the nourishment of the patient by bland food in liquid form In some cases nutrient enemata were employed, and the use of saline intra-venous injections was also reported No special mode of treatment has seemed to influence the disease in an appreciable manner The favorable change in the epidemic and its final subsidence are generally referred to the lower temperature, and particularly to the frosts of the middle of November

In review we have the outbreak of a limited epidemic in the centre of a large city manifesting itself especially among rag pickers, and for a time apparently confined to them and to their habitat alone Afterward the disease spread to a moderate extent, and was reported from nearly every part of the city The patients were almost without exception persons who were underfed, insufficiently protected, dissolute, and intemperate. To my knowledge not one stranger was attacked during the entire epidemic, and no English-speaking person was known to suffer from the disease.

But few residents of Paris left the city, and there was no appearance of fright, much less of panic, to be observed. The disease is entirely quenched, and will doubtless not recur until the approach of warmer weather, when it will, in the opinion of most of those with whom I have spoken, again appear, and will far exceed the present epidemic, both in the extent of its ravages and in severity. The disease has already been recognized in Nantes, in Yport, in Brussels, in Marseilles, in Toulon, it has crossed the border into Northern Italy, it has invaded Spain, and it has been reported in some other places. It is to be feared that the advent of spring will arouse the disorder anew, and that the entire west of Europe will be devastated by it.

The epidemic just ended has not contributed anything material in the support of the theories of Professor Koch as to the origin, or "Wesen," of cholera. I have not been able to find, either here or in Berlin, any ardent support for the claims of the comma bacillus as the cause or essential element of the disease.

The importance of the bacillus of tubercle is generally conceded, and in Berlin I saw specimens which were made for purposes of diagnosis, thus showing that the presence of the organism is recognized as of practical value in daily routine, but the same authority spoke of the bacillus of cholera with some degree of distrust, and expressed the opinion of the profession as being that the bacillus is a concomitant, but not clearly the cause, of the disease.

It is yet too early for the official reports of the sanitary authorities and the medical department upon the recent epidemic in Paris, but I am led to believe that efforts are being made to utilize the presence of the disease as a study for guidance in the expected revival of the disorder in the near future.

It is to be hoped that this important information may be published in advance of the threatened outbreak of cholera, but, in the meantime, every precaution is being employed to secure the best possible sanitary conditions, which must favor a mitigated severity in any epidemic disease. A. N. B.

BERLIN LETTER.

BERLIN, Nov. 24, 1884.

Wandering Kidney — Hydronephrosis — Perinephritic Abscess—Abdominal Fistula.—In my last letter I mentioned a case of wandering kidney which I saw at the poli-klinik of Dr. Leopold Landau, Privat Docent. There is so much of general interest in this subject, and so much of especial merit in this case that I translate its history from "Die Wanderniere der Frauen"—a small brochure too little known in America, and yet one in which the whole subject is reviewed by Dr. Landau in a masterly manner. "C. M., 60 years old, has borne two children, one at forty and the other thirty-six years age. At her last confinement she had a prolapse of the uterus. For the last ten years she has suffered from pain in the loins, constant uneasiness in the abdomen, cardialgia, gastric derangement, dragging pain in the loins and pressure upon the bladder. About eight years ago she first noticed a wandering swelling in the abdomen, the pain, however, from time to time, disappeared, and several physicians who examined the case thought it an echinococcus of the peritoneum, or an ovarian tumor, or a tumor of the liver. On the 14th of Sept., 1879, she entered my poli-klinik.

"*Present Condition.*—A pale, emaciated woman, with prolapse of the anterior vaginal wall and uterus. In the right lumbar region a firm, elastic, round tumor could be felt, which extended upwards to the liver (being disguised by the latter), inwardly as far as the linea alba, outwardly to the axillary line, and downward to within 3 ctm. under the level of the umbilicus. By pressing downward a sulcus can be made out between it and the liver. The percussion sound over the tumor is a dull tympanitic, and is dull at its highest point. In the line of the axilla it is dull. Puncture is made with a fine Dielafoy needle, and about 3 cbctm. of water-like fluid is withdrawn, which is white by transmitted light, clear without any form elements, with no albumen, and rich in chlorides. The diagnosis was between echinococcus of the liver or kidney, or a hydronephrosis of a wandering kidney. After another examination of the woman in different positions, on the 20th Sept., 1879, and after another puncture (removing also about 3 cbctm.), I fixed upon the following day for the operation. On this day, however, the swelling disappeared, and in its place percussion disclosed the intestine only. It was impossible to arrive at any definite conclusion, even after elaborate palpation and examination. On questioning the patient, who found herself in good condition, she stated that after yesterday's examination she had voided a very large amount of clear light urine, which did not seem to be at all strange to her, as the amount of her urine varied. The urine itself was normal. It was now questionable whether the contents of the cyst had emptied itself through the fine puncture of the sac into the peritoneum, or whether it had emptied itself through the natural channels. In the former case the diagnosis would be doubtful, in the second it would be hydronephrosis. After an examination of different parts of the body, especially in the knee-elbow position, the sharply-bent and tortuous urethra might have unwound itself, or pressure upon the sac having been removed (by puncture), the valve-like opening might have opened itself. For the first weeks, however, the diagnosis was doubtful, as the pathognomonic urticaria of echinococcus was not present, and there was no re-appearance of the tumor. Again, in Feb., 1880, the patient returned, complaining of an unbearable pressure in the abdomen, and with the same train of symptoms as formerly. The diagnosis of hydronephrosis was now certain, and was confirmed by a careful chemical examination by Dr. Lewin (Priv. Docent) of a large quantity of fluid which had been withdrawn by aspiration. 'The fluid was not clear as far as could be seen by gas-light, it was of alkaline re action, the cloudiness disappeared upon the addition of nitric acid This showed it to be due to phosphatic salts Uric acid crystals were not to be found On account of the uncertain light the test for uric acid by the *murexid* re action was not shown Nevertheless it was certainly shown that the urates were present, for after the precipitation of the phosphates the addition of mercuric nitrate to the fluid a white precipitate of the *urate of mercurous oxide* was seen The urates are to be shown more easily by the change into nitrate of urea When the fluid, after the addition of nitric acid, was left to natural evaporation, there were found very characteristic rhomboidal, tile like crystals, overlapping one another, of nitrate of urea ' Some time after this it was my good fortune to witness the return of the cyst-filling and emptying process, with the same symptoms as regard the excretion of urine At last the sac did not disappear again The general condition of the patient was growing worse, and a trip to Carlsbad, on account of her gastric troubles, was advised A continued fever followed upon this trip Formerly the puncture gave exit to a clear fluid, now it contained many pus corpuscles, so that the time of operation was not to be postponed The tumor had grown larger, was more tense, and was very sensitive to the lightest touch On the 20th June, 1880, I undertook the operation, starting the incision from the bend of the ribs upon the right, parallel with the ob int muscle, toward the umbilicus—a distance of 12 ctm This disclosed a fleshy-looking cyst-wall, which, on account of its great tension, could not be grasped by the hand, hence it was punctured, and about 300 cbctm of pus like fluid were withdrawn, after which the incision was extended 3 ctm to the axillary line It was now easy to grasp the tumor upon all sides It was now seen to extend up to the liver, and to be attached to it, downward and anteriorly it was attached to the gut, and outwardly to a *second* tumor, which extended to the spinal column Puncture showed this second tumor to be an abscess caused by perinephritis Its contents were thicker, tougher, and more like pus than the fluid in the hydronephrotic sac On account of the perinephritic abscess total extirpation was out of the question The walls of the cyst were attached by sutures on each side to the abdominal parietes, the sutures being inserted vertically to the incision By this means the peritoneum was protected from fluid entering its cavity, which proved to be of great importance, as the walls of the perinephritic abscess gave way, and an abundance of pus-like fluid escaped, when an attempt was made to grasp the tumor from behind and lift it out of the cavity A second incision, in the same direction as the first, is made into the sac, whose walls have been sutured to the abdominal parieties, through the perinephritic abscess, which is separated by the walls of the atrophied kidney, thus establishing a common wound cavity The part of the hydronephrotic sac lying next to the anterior abdominal parieties is not the usual pelvis of the kidney, but the compressed atrophied kidney substance, which, upon incision, bled profusely, and had to be ligated *en masse* The fluid thus obtained was like pus The hydronephrotic sac, larger than a child's head, was everywhere covered with the compressed kidney substance The opening of the ureter cannot be found The sac is now attached by twelve more sutures, and drainage is established On the 19th of July the whole wound is healed, having only an opening as large as the end of the finger, at the inner angle of the wound, through which a drainage tube 14 ctm long is easily inserted into the cavity which gives exit to the urine, which was first excreted in small quantity, but afterward in greater abundance The tube also permitted the washing out of the cavity The pus like fluid at first secreted soon cleared up, and became more like urine The sac is growing smaller The flattened, atrophied kidney chalices are getting thicker and hypertrophied After three months and a half the ligatures came out The papilla renalis can be felt at the inner edge of the wound, somewhat atrophied The patient follows her daily avocations without any inconvenience "

The case is an interesting curiosity of medical literature In my next letter I shall describe the treatment of *syphilis by massage*

NECROLOGY

Martin, Henry A, m d A man's best epitaph is written in his deeds The emphasis of this truth finds expression in the history of Dr Henry A Martin, who died at his residence, in Boston, December 7

Dr Martin was born in London, England, July 23, 1824, and was the eldest son of Henry J Martin, Esq, m r c s The family is traced down the centuries through a long line of distinguished sires, ennobled by race and deed Gen James Agnew, who was killed at Germantown while in command of the British forces, was his great grandfather He was the grandson of the Earl of Eglintonn, and was in command of British troops in Boston at the outbreak of the Revolution

Dr Martin was graduated at Harvard in 1845, and commenced the practice of his profession in the Roxbury district in 1847, where during an entire generation he has labored with a steadiness of purpose and faithful zeal equalled by very few in any calling His attention was early called to the necessity of more thorough and systematic methods of vaccination to prevent the ravages of small-pox, and so widely was he recognized as the authority upon this subject, that upon the first serious appearance of that disease among our soldiers during the Rebellion he was summoned by the War Department to superintend the vaccination of the troops, going early to Fortress Monroe and other posts for that purpose He then entered the service as one of the first "Surgeons of Volunteers," was Medical Director of Southeast Missouri two years, in charge of hospitals at Ironton and Cape Girardeau, was Medical Director at Norfolk and Portsmouth, Va, and Surgeon-in-Chief First Division Second Army Corps (General Miles), and was breveted Lieutenant-Colonel for "gallant and meritorious service"

After repeated failures to secure the successful cultivation of animal vaccine in America, Dr Martin sent an agent to Europe, had the methods there used in propagating virus carefully studied, and with virus thus obtained he inoculated a herd of young animals, vaccinating and re vaccinating at regular intervals, and in this way secured an unbroken series of the Beaugency stock of virus, which has been continued until the present It is very probable that no man, even including the immortal Jenner, ever gave a more careful attention to the study of small-pox and the means of its prevention than Dr Martin, and, except to the great discoverer, the world owes no man in this field of preventive medicine an equal debt of gratitude

Dr Martin has been indefatigable in his gathering of everything possible published upon this subject, and his literary collection is believed to be unique By his aid a very considerable number of epidemics have been eradicated and numberless lives saved His report on animal vaccination made to the American Medical Association, 1877, was very flatteringly reviewed and quoted from by all the leading medical journals and authorities in Europe

Many years since he became interested in the use of elastic compression applied in surgery This, after many experiments in great variety, resulted in the giving to the profession the pure rubber bandage now world-wide known by his name This he applied to a great variety of purposes In varicose ulcer and synovitis of the knee it has proved of such exceptional service that it may be safely classified as one of the most valuable contributions in modern surgery He also originated the operation for tracheotomy without the use of tubes

Dr Martin was a man of fine physique and presence, possessed an excellent voice, an exceptional command of language, was a ready, fearless debater, once met as an opponent never to be forgotten, a firm and steadfast friend He denounced show and pretence with Quixotic vehemence, while he recognized true worth and learning In the literature of medicine he was a master, and never wearied in the study of history Many a supposed invention of modern surgery has he traced to its real origin and demonstration in the long forgotten work of some ancient author

He was particularly fond of art, especially that of engraving His collection is filled with the rich treasures of the great masters, and his library is one of the most valuable medical libraries in Boston

Knowing for eighteen months that he was the victim of an incurable disease, he kept steadily and calmly on in the usual routine of his life, seeing patients and pursuing his studies until two days before his death He leaves a widow and four sons, upon two of whom the professional mantle has fallen The following is a list of his most valuable contributions, and he leaves voluminous manuscripts, which in the hands of his sons, might be edited as a volume of interest and value

THE PHYSIOLOGICAL ACTION OF COCAINE ON THE COMMON FROG, WITH SPECIAL REFERENCE TO ITS ACTION ON ORGANS AND TISSUES[1]

BY HERMAN M BIGGS, A B , M D , NEW YORK

In the following experiments the hydrochlorate of cocaine, prepared by Merck, of Darmstadt, was used It is uncrystallized, of a dull white color, has a slightly bitter taste, nearly neutral reaction, and is very soluble in water, alcohol, ether and chloroform The solutions used were all made with water, and were 1, 2 and 4 per cent in strength

Local Action —On the skin and mucous membrane If the foot of a frog be immersed for a few minutes in a solution of cocaine (2 per cent), very marked anæsthesia of the skin is produced , or, if a solution (2 or 4 per cent) is applied to the mucous membrane of the mouth, the same action is observed

On the eye When a few drops of a 4 per cent solution are instilled into the eye of a frog, there is caused, after a short time, almost complete anæsthesia of the conjunctiva and cornea The action on the pupil is not constant, but usually a moderate degree of mydriasis is produced

General Action —The effects of cocaine given by hypodermic injection begin to manifest themselves very quickly, and in a few minutes have reached their maximum When large doses are given, the action is seen almost immediately, and the duration and severity of the symptoms are in proportion to the amount used After small doses the animals begin to recover at the end of a few minutes , but if the quantity administered is large, it is many hours and it may be several days, before the effects have entirely disappeared Lethal doses are from 04 grm upwards and when death occurs from the effects of cocaine, it is only after the lapse of 24 or 36 hours

Small Doses —When a small toxical dose of cocaine (005 grm) is injected under the skin of a frog there are usually at first no perceptible effects In some cases there is a short period of excitement, but this is not always present, nor is it as a rule, very strongly marked when present The frog soon becomes quiet, he moves less quickly after stimulation is applied, and his respirations are somewhat increased in number In a few minutes he becomes perfectly motionless, and changes his position only after considerable irritation, and then with an evident effort Presently his head drops, the respirations become slower and the pupils somewhat dilated Twenty or twenty-five minutes after receiving the poison he lies flat on his abdomen and neck, with the posterior extremities extended, and is unable to raise or balance himself If strong stimulation is applied, he makes a vain effort to spring, which sometimes takes the form of a partial clonic convulsion There is marked loss of power over his extremities, and this appears earlier and is much greater in the posterior than in the anterior The action of the heart is somewhat slower than normal In a short time he begins to recover, his respirations are more frequent and deeper, he raises his head and is able to balance himself when not disturbed The last function to return is complete voluntary power in his limbs An hour or an hour and a half after receiving the poison, the animal has become quite normal again

Moderate Doses —After moderate toxical doses (01 grm) given hypodermically, as after small doses, there is sometimes a short period of excitement , but this, even when present, soon gives way to the depressing action of the drug The animal becomes perfectly quiet, the respirations slow and superficial, and the heart's action diminished in both force and frequency At the end of seven or eight minutes the frog can no longer support himself and lies extended at full length His toes being pinched he makes two or three powerless efforts to move and then remains quiet The loss of power and also of sensation appears earlier, and is more marked in the hind legs than in the front legs, as in the first experiment The pupils are somewhat dilated After about twenty minutes, he becomes perfectly relaxed and remains in any position in which he is placed His respirations are imperceptible and only weak reflex movements occur after severe mechanical stimulation, although a moderately strong interrupted current calls forth muscular contractions

An hour later the animal lies in the same position Neither the action of the heart nor any respiratory movement is perceptible, and the reflexes are less marked than before About two hours and a half after receiving the poison, the frog begins to show signs of recovery It makes some slight voluntary movements and the reflexes become stronger Three

THE PHYSIOLOGICAL ACTION OF COCAINE ON THE COMMON FROG, WITH SPECIAL REFERENCE TO ITS ACTION ON ORGANS AND TISSUES[1]

BY HERMAN M BIGGS, A B , M D , NEW YORK

In the following experiments the hydrochlorate of cocaine, prepared by Merck, of Darmstadt, was used It is uncrystallized, of a dull white color, has a slightly bitter taste, nearly neutral reaction, and is very soluble in water, alcohol, ether and chloroform The solutions used were all made with water, and were 1, 2 and 4 per cent in strength

Local Action—On the skin and mucous membrane If the foot of a frog be immersed for a few minutes in a solution of cocaine (2 per cent), very marked anæsthesia of the skin is produced, or, if a solution (2 or 4 per cent) is applied to the mucous membrane of the mouth, the same action is observed

On the eye When a few drops of a 4 per cent solution are instilled into the eye of a frog, there is caused, after a short time, almost complete anæsthesia of the conjunctiva and cornea The action on the pupil is not constant, but usually a moderate degree of mydriasis is produced

General Action—The effects of cocaine given by hypodermic injection begin to manifest themselves very quickly, and in a few minutes have reached their maximum When large doses are given, the action is seen almost immediately, and the duration and severity of the symptoms are in proportion to the amount used After small doses the animals begin to recover at the end of a few minutes, but if the quantity administered is large, it is many hours and it may be several days, before the effects have entirely disappeared Lethal doses are from 04 grm upwards and when death occurs from the effects of cocaine, it is only after the lapse of 24 or 36 hours

Small Doses—When a small toxical dose of cocaine (005 grm) is injected under the skin of a frog there are usually at first no perceptible effects In some cases there is a short period of excitement, but this is not always present, nor is it as a rule, very strongly marked when present The frog soon becomes quiet, he moves less quickly after stimulation is applied, and his respirations are somewhat increased in number In a few minutes he becomes perfectly motionless, and changes his position only after considerable irritation, and then with an evident effort Presently his head drops, the respirations become slower and the pupils somewhat dilated Twenty or twenty-five minutes after receiving the poison he lies flat on his abdomen and neck, with the posterior extremities extended, and is unable to raise or balance himself If strong stimulation is applied, he makes a vain effort to spring, which sometimes takes the form of a partial clonic convulsion There is marked loss of power over his extremities, and this appears earlier and is much greater in the posterior than in the anterior The action of the heart is somewhat slower than normal In a short time he begins to recover, his respirations are more frequent and deeper, he raises his head and is able to balance himself when not disturbed The last function to return is complete voluntary power in his limbs An hour or an hour and a half after receiving the poison, the animal has become quite normal again

Moderate Doses—After moderate toxical doses (01 grm) given hypodermically, as after small doses, there is sometimes a short period of excitement, but this, even when present, soon gives way to the depressing action of the drug The animal becomes perfectly quiet, the respirations slow and superficial, and the heart's action diminished in both force and frequency At the end of seven or eight minutes the frog can no longer support himself and lies extended at full length His toes being pinched he makes two or three powerless efforts to move and then remains quiet The loss of power and also of sensation appears earlier, and is more marked in the hind legs than in the front legs, as in the first experiment The pupils are somewhat dilated After about twenty minutes, he becomes perfectly relaxed and remains in any position in which he is placed His respirations are imperceptible and only weak reflex movements occur after severe mechanical stimulation, although a moderately strong interrupted current calls forth muscular contractions

An hour later the animal lies in the same position Neither the action of the heart nor any respiratory movement is perceptible, and the reflexes are less marked than before About two hours and a half after receiving the poison, the frog begins to show signs of recovery It makes some slight voluntary movements and the reflexes become stronger Three hours later he turns over on his belly, and irritation calls forth characteristic clonic contractions There are as yet no signs of returning respiration In twelve or fourteen hours the frog has entirely recovered

---

[1] These experiments were made in the physiological laboratories of Profs Dubois Reymond and Christian, in Berlin

Large Doses —When large toxical doses of cocaine (025 grm) are given to a frog by hypodermic injection, the effects begin to manifest themselves almost instantly All the phenomena observed in the previous experiments, here follow each other in rapid succession and in a much more intense form There is no period of excitement In two or three minutes respiration is labored, pupils dilated with opisthotonus, heart's action slow and reflexes greatly diminished The frog has a very anxious expression and in a few minutes more he drops motionless on the table, extended at full length There is only a weak reflex after severe irritation Respiration ceases with the lungs in inspiration After many hours, if the dose has not been lethal, signs of returning life begin to show themselves, but it is two or three days before the animal has entirely recovered After the exhibition of a lethal dose, the heart continues to act for twenty-four or thirty six hours and then stops in diastole

Action on the Heart —When a frog has been poisoned by cocaine by hypodermic injection, the action of the heart is either unaffected or there is a diminution in the frequency of its pulsations After very small doses (001 grm) there is no perceptible influence When a somewhat larger amount is given (005 grm), the frequency of the heart's action is reduced from eight to twelve pulsations a minute, and it becomes irregular and intermittent In the course of two or three hours the influence of the drug has passed off and the action of the heart becomes perfectly normal again Large toxical doses (025 grm) cause an almost immediate reduction in the number of pulsations to six or eight per minute The heart becomes engorged with blood and its action is very much labored and irregular The alternate action of the auricles and ventricle is replaced by an irregular action, and long pauses occur in the pulsation of the ventricle The ventricle is affected earlier and more severely than the auricles, and when paralysis finally occurs, if a lethal dose has been given, the ventricle ceases to pulsate a long time before the auricles

Experiment I —Medulla destroyed Heart exposed ♏ iv sol cocaine (1 per cent)= 0025 grm injected hypodermically

Time	*Minutes after Cocaine given*	*Pulsations of Ventricle in 15 sec*	*Pulsations of Auricles in 15 sec*	*Amt Cocaine*	*Remarks*
11 20		12 12	12 12	grm 0025	
11 24		12 12	11 11		
11 26	2	11 11	11 11		
11 30	6	11 11	11 11		Action somewhat labored
11 40	16	10 11	10 11		
11 45	21	10 11	10 11		
11 55	31	10 11	10 11		
12 05	41	11 11	11 11		

Experiment II —Medulla destroyed, heart exposed ♏ viij sol cocaine (2 per cent)= 01 grm injected hypodermically

Time	*Minutes after Cocaine given*	*Pulsations of Ventricle in 15 sec*	*Pulsations of Auricles in 15 sec*	*Amt Cocaine*	*Remarks*
3 43		11 12	11 12		
3 45		12 12	12–12	01grm	
3 47	2	11 11	11 11		
3 57	12	8 8	8 8		Irregular Occasional long pauses
4 01	16	8 8	8 8		
4 04	19	8 9	8 9		
4 10	25	7 7	7 7		Irregular and intermittent Occasional pauses of ventricle while auricles continue to act
4 15	35	7 7	8 9		
4 30	50	7 8	8 9		
4 36	56	7 8	10 9		
4 52	1h 12m	8 9	9 8		
5 00	1h 20m	9 9	9 9		Acting regularly

Experiment III —♏ x sol cocaine (4 per cent) 025 grm injected hypodermically

Time	*Minutes after Cocaine given*	*Pulsations of Ventricle in 15 sec*	*Pulsations of Auricles in 15 sec*	*Amt Cocaine*	*Remarks*
4 12		11 12″	11 12″	grm 025	
4 14		11 12	11 12		
4 17	3	4 3 4	8 9		Very irregular and labored in its action
4 21	7		7 8		
4 24	10	3 3 3	6 6		Heart engorged with blood Ventricle cannot completely empty itself
4 27	13	3 2 3	4 5		
4 33	19	3 7	6 6		Action very irregular and intermittent
4 35	21	3 2 0	6 6		Pause of 15 sec in action of ventricle
4 40	26	0 0 0	4 4		Pause of 60 sec in action of ventricle
4 50	36	3 2 0	5 5		
5 00	46	0 0 3	5 6		

If the heart of a frog be exposed and three or four minims of a (4 per cent) solution of cocaine be injected directly into the ventricle, the heart is immediately paralyzed and stops in systole If now, as a contra experiment, into the heart of another frog the same amount of water or normal salt solution be injected, no effect is produced save that arising from the physical injury, and this soon passes away, but afterwards the injection of this same quantity of a (4 per cent) solution of cocaine causes, as before, immediate paralysis of the heart in systole

Again, when three or four minims of the same solution of cocaine are injected into the median abdominal vein, or into one of the great veins of the heart, paralysis either immediate or after two or three beats results In these cases the heart stops in diastole

The local application by means of a camel's hair pencil of a weak solution (1 per cent) of cocaine to the heart muscle causes a temporary diminution in the frequency of its pulsations

Experiment IV—Medulla destroyed Exposed heart

Time	*Pulsations of heart in 1 minute*	*Amount Cocaine*	*Remarks*
10 25	33		
10 50	34	Cocaine in 1 per cent solution	
11	34		
11 04	24		Heart somewhat distended with blood
11 13	29		
11 18	24		
11 34	34		
11 36	17		Action labored and irregular, but soon becomes normal in frequency and character
11 44	30		
11 47	17		Irregular Heart engorged with blood
12 10	26		

Action of Cocaine in Substance on the Heart—*Experiment V*—Medulla destroyed, heart exposed Cocaine in substance applied to both auricles and ventricles In about three minutes the heart had ceased to pulsate The ventricle is in systole, and the auricles are in diastole

Experiment VI—Medulla destroyed, heart exposed Cocaine in substance applied to heart After four minutes the heart had ceased to pulsate Ventricle is in systole, and the auricles in diastole

Four or five hours later, in neither of these cases had the heart commenced again to act (See Experiment VII)

Experiment VII —Conditions same as previous cases Results same The ventricle is firmly contracted and pale The auricles large and distended with venous blood In the last case, eighteen hours later, the heart was found to be again pulsating slowly and feebly It continued to act for about six hours, and then stopped In a number of succeeding experiments it was observed that in most cases, after many hours, the heart commenced again to act but this was not true in all cases, and when the solution was injected into the cavity it never occurred In all cases the ventricle was in systole, and in all but one the auricles were in diastole

Cocaine in substance applied to either one of the auricles, or to the ventricle separately, caused a temporary paralysis of the respective portions of the heart, and a diminution of the frequency of the pulsations of the heart itself, but not paralysis, unless it was used in large quantity

Influence on Respiration —Small toxical doses of cocaine (0025 grm) cause at first a slight increase in the frequency of the respirations, but soon they become much diminished, and are reduced to six or eight per minute These are very superficial, and sometimes, even with these small doses, all respiratory movement disappears for a short time

After medium-sized doses (from 005 grm to 01 grm), the temporary rise in the number of respirations per minute is less marked, and the depressing effects of the poison are more quickly observed The decrease in the frequency is much more rapid than after small doses, and respiration usually becomes imperceptible in about twenty-five or thirty minutes

With large toxical doses (from 025 grm upwards) there is no semblance of a temporary increase The respirations rapidly diminish in number and change in character, and usually in ten minutes have entirely disappeared After these large doses respiration stops after a full inspiration, in the other cases apparently after expiration Respiration does not appear again until after at least twenty-four hours, and often it is a much longer time

Experiment VIII—♏ iv sol cocaine (1 per cent) = 0025 grm , injected hypodermically Frog free under glass jar

Time	*Minutes after Cocaine given*	*Respirations in 15 sec*	*Amt Cocaine*	*Remarks*
10 15		18	0025	
10 17	2	20		
10 20	5	24		Irregular but rather deep

11 07	17	9		Very superficial
11 15	25	8		Scarcely perceptible
11 28	38	None		

Experiment X —♏ x sol cocaine (4 per cent)= 025 grm injected hypodermically Frog free under glass jar

Time	*Minutes after Cocaine given*	*Respiratio's in 15 sec*	*Amt Cocaine*	*Remarks*
11 33		18	grm	
11 35		18	025	
11 37	2	16		Difficult respiration
11 38	3	14		
11 39	4	12		Very superficial
11 40	5	None		

ACTION ON NERVOUS SYSTEM

Spinal Cord —Very small doses of cocaine slightly increase the reflex irritability of the spinal cord for a short time When larger doses are given, the period of heightened reflexes is very short (if it is at all present) and then follows a period of much longer duration, when they are decidedly diminished After large toxical doses, there is no period of greater irritability, but almost immediately the general reflexes are very much lessened, and there is soon almost complete loss of all response to mechanical or chemical stimulation Loss of response to strong electrical stimulation never occurs except just before death

Sensory and Motor Nerves —(From B von Anrep) Small doses heighten the irritability of the sensory fibres without having any effect on the motor filaments Large doses cause after a slightly increased irritability of the sensory fibres of short duration a diminution of the same Large toxical doses almost completely paralyze the sensory filament, and diminish greatly the irritability of the motor Tactile reflexes are much diminished The pneumogastrics are completely paralyzed after doses of moderate size The small doses have no perceptible influence on the inhibitory fibres of the pneumogastrics After the poisoning they either remain as before responding to the same strength of current, or they are wholly paralyzed

Experiment XI —Heart exposed Both pneumogastrics divided

Time	*Contract's of the Ventricle in 15 sec*	*Contract's of the Auricles in 15 sec*	*Amt Cocaine*	*Remarks*
8 30	13 14 14	13 14 14

	5 5 5	8 8 8		Stimulation of left P
9 20	5 4 5	8 8 8		
10 00	2 2 2	4 5 4		
11 00	2 1 2	3 4 3		

Local Action on Nerve-Trunks —Cocaine in weak solution (1 per cent) When applied directly to the nerve-trunks after a very transient period of increased irritability, depresses greatly and finally paralyzes the nerve If it is applied in strong solution (4 per cent or more), the paralyzing action is almost instantaneous, and is attended by no period of increased irritability If, however, the solution is not left in contact with the nerve for too long a time (and the nerve is still in its natural connection), it will regain all its former irritability in from one and a half to two hours

Experiment XII —A preparation of the sciatic nerve and the gastrocnemius muscle of a frog is made in the usual manner, and in as fresh a state as possible, is arranged on the muscle-telegraph of Prof Dubois Reymond, and is then connected with the induction coil of his Sliding Induction apparatus, a simple key intervening The nerve is placed in a moist chamber and non-polarizable electrodes are used A 1 per cent solution of cocaine is applied by means of a camel's-hair pencil to the nerve from time to time The figures in the second column indicate in centimetres the distance that the secondary coil is from the primary at the time that contraction occurs

Time	*Centimetres*	*Amt Cocaine*	*Remarks*
10 10	70	1%	
10 20	43		
10 25	37	1%	
10 30	33		Contractions very feeble Cannot produce tetanus
10 35	No response		

Control —*Experiment XIII* —Conditions same as last Water used first, then solution of cocaine

Time	*Centimetres*	*Water and Sol Cocaine*	*Remarks*
10 15	93	Water	
10 20	97*		97 is limit of the distance of second coil from first
10 30	97		
10 40	97		
10 45	97	Cocaine in 1% sol	Active contractions
11 15	No response		The irritability rapidly diminished after the application of a solution of cocaine, and at the end of 30 minutes the nerve was completely paralyzed

Experiment XIV —Conditions same as XIII

Time	*Centimetres*	*Water or sol Cocaine*	*Remarks*
11 10	87	Water	
11 20	97		
11 40	97		Very active contractions
11 50	46		
12 05	42		
12 35	36	Cocaine 1% sol	After being in water for one hour and a half, all irritability disappeared in six minutes when cocaine applied
12 41	No response		

---

*The irritability of a nerve is often greater a short time after removal than at time of removal

Experiment XV—Conditions same as XIII Cocaine in 4 per cent sol used

Time	*Centimetres*	*Sol Cocaine 5%*	*Remarks*
10 50	50		
10 55	50	4%	
10 56	47		
10 59	No response		In a number of other experiments with the action of a 1% sol on nerves, all irritability had disappeared in from 15 to 35 minutes

Experiment XVI—If a nerve muscle preparation be made from a frog poisoned by cocaine, the irritability of the nerve is found to be much diminished (This is also true of the muscle) The strength of current required to produce a muscular contraction is decidedly greater than for that from a normal frog The muscular pulsations are shorter and less powerful, and it is impossible to produce tetanic contractions (if the amount of the drug given has been at all large) When the interrupted current is passed through the nerve for some time, there are several short, quick, feeble pulsations of the muscle caused and then there is no more response The contractions are very similar to those produced by stimulation applied to a nerve poisoned by the local application of a solution of cocaine

Experiment XVII—Medulla destroyed Sciatic nerve of one leg carefully exposed, as little injury being done to the vessels as possible The irritability of the nerve is accurately determined with the sliding induction apparatus A solution of cocaine (1 per cent) is then applied till the nerve only responds to the stimulus of a very strong current Normal salt solution is then substituted for the solution of cocaine, and in the course of an hour and a half the irritability of nerve has completely (or almost completely) returned

Experiment XVIII—Medulla destroyed Sciatic nerve exposed on one side and a cord is passed carefully under it and around the limb so as to include all the tissues of the limb except the nerve, and is then firmly tied—the frog is poisoned by a moderate dose of cocaine The nerve of the other leg is now exposed, and the comparative irritability of the nerves on the two sides is determined It is found that it requires a much stronger current to produce a muscular contraction in the leg not shut off from the circulation than in the bound leg If the irritability of the nerves is tried from time to time, it is found that the irritability gradually returns to the poisoned nerve, and that in the course of an hour and a half or two hours, it has become as great as that of the protected leg From these two experiments it is seen that the irritability of nerve-trunks, whether diminished by the local application of a solution of cocaine or by cocaine given by hypodermic injection, is regained in about the same length of time It would therefore seem probable that the action in both cases was a purely local one

Experiment XIX—If the nerve from a nerve muscle preparation be immersed for a few seconds in a solution of cocaine and then be removed, it is found that the irritability is very much increased The slightest touch of a steel instrument throws the muscle into violent tetanic contractions If the nerve be now again immersed for a longer time, the irritability becomes very much diminished and is finally lost to all forms of stimulation When the nerve is first placed in the solution, no irritation is caused by the immersion

The influence of cocaine on the nervous system would not be complete without an allusion to the apparently marked effects of the drug on the power of coordination, which all frogs poisoned by cocaine show It is particularly manifest after doses of moderate size

Action on Striated Muscles—Small doses of cocaine given hypodermically have little effect on the excitability of the voluntary muscles, but large doses diminish their excitability very decidedly The character of the muscular contraction called forth by electric stimulation is greatly altered The pulsations are shorter, slower, and more feeble, and the muscular excitability is soon exhausted The local action of cocaine on muscular tissue is very similar to that found in general poisoning

Experiment XX—Gastrocnemius of frog without the nerve is prepared in the usual manner, and is arranged on the muscle-telegraph, and is then connected with the induction coil of the sliding induction apparatus The numbers in the second column represent the number of centimetres that the induction coil was distant from the primary coil when contraction occurred Cocaine in 1 per cent solution was applied to the muscle by means of a camel's-hair pencil

Time	*Centimetres*	*Amt Cocaine*	*Remarks*
12 03	24	1%	
12 05	23		
12 07	18		
12 10	17		
12 11	17	1%	
12 18	16		
12 22	16	1%	Responds feebly, and after two or three contractions responds no more
12 26	15		
12 30	13		Very feeble response to very strong current

The muscle retains the slight excitability, remaining at about this point for some time

Experiment XXI—Preparation and arrangement same as in Ex xx sol cocaine 2 per cent used

Time	*Centimetres*	*Cocaine applied*	*Remarks*
12 35	26		
"	26	2 per cent	
12 38	20		
12 40	18		Quick, short, pulsations
12 44		2 per cent	
12 50	16	2 per cent	
12 55	15		Contractions slow and feeble
1 07	12		Responds very feebly
1 15	5		Scarcely perceptible contractions to very strong current
1 25	No response		

The application of cocaine in substance to muscle produces a gradually decreasing excitability until after twenty or twenty-five minutes there is complete loss of all excitability and there is no response to the strongest interrupted current It requires many hours for a muscle to regain its excitability when it is to any considerable extent destroyed by either the local or the constitutional action of cocaine Here again the local and the general actions of the drug are very similar

In conclusion, then, the action of cocaine on the frog may be summed up as follows

1 It has a powerful local anaesthetic action on the skin, mucous membrane and the eye It usually produces mydriasis

2 It has a depressant action on the heart, reduces the force and frequency of its pulsations and finally paralyzes it (first the ventricle and then the auricles) in diastole

3 In small doses it at first slightly increases the number of the respirations, then decreases them, and in large doses diminishes them rapidly from the first, finally causing death from a paralysis of respiration

4 It at first slightly heightens, and then greatly depresses the reflex action of the spinal cord in small doses Large doses depress from the first

5 Small doses at first slightly increase the irritability of the sensory nerves, then depress their irritability, and large doses depress from the first

6 Both large and small (not very small) doses have a depressant action on the motor nerves

7 It paralyzes the pneumogastric nerves

8 Doses of moderate size diminish the excitability of the striated muscles

9 The local application of cocaine to any of the more highly constituted organs or tissues causes a temporary cessation of their functional activity

10 From the local and constitutional action on the different organs and tissues, it is rendered probable that its general action is wholly a local one, exercised on all parts for which it has a chemical affinity, through its presence in the blood

The results of these experiments would seem to indicate the use of cocaine in tetanus and strychnia poisoning

The writer hopes to be able to report in a short time the results of similar experiments on the warm blooded animals, with experiments on the antidotal action of strychnia and cocaine

FRAGMENTARY COMMENTS ON SOME OF THE PRINCIPAL METHODS OF OPERATION FOR "STONE IN THE BLADDER"

With Special Reference to Allarton's Method, Also in Combination with Lithotripsy, Urethro-Lithotripsy, Urethrotomia Lithotriptica, Including Besides Critical Remarks Upon the Discussion of the Progress Made in Lithotripsy and "Lithotomy" at the Late International Medical Congress held in London, England, and divers other subjects comprising the Urinary Organs

BY M SCHUPPERT, M D , OF NEW ORLEANS, LA

[CONTINUED]

The Lateral and Bilateral Cystotomy (*"La Taille" of the French*) —Some authors of to day recognize only two main methods of *cystotomy*, 1, *the inferior C*, where the membranous and prostatic portion of the urethra, with the neck of the bladder, are cut, and of which they cause two subdivisions, or, *the lateral*, and, *the bilateral C*, and, 2, *the superior C*, whilst the pærineal median and others are simply mentioned Of all the different methods of cystotomy the lateral section is preferred by most surgeons, and most frequently performed since its introduction into England by Cheselden So far it has also given the best results in children previous to puberty The best advice in performing the operation is to keep the point of the knife high up, on account of the high position of the bladder, which, also, by being partially filled with warm water, will descend lower

Concerning the *bilateral operation* we find that the authors are of different opinions With some the body of the prostate and the membranaceous part of the urethra have to be divided, while others want the neck of the bladder included, as *Le Dran* and *Senn Vidal de Cassis* wanted even the neck incised in four different opposite directions, to accomplish which *Colombat* constructed a separate curious knife, which he called "*lithotome quadruble*"

In cases with extremely hard stones too hard for crushing with the common instruments, the bilateral section has been recommended, though others preferred the sectio alta, or even *recto cystotomy* Performing the bilateral operation the arteria transversalis is almost always, and the bulbo urethralis occasionally, cut I have seen the latter happen once, and a terrible bleeding to ensue, which the operating surgeon had the greatest difficulty in arresting The rectum in the cavum ischio-rectali is also considered

liable of being injured, and a fistula remaining here gave formerly a great deal of trouble in its cure With the increase in size of the calculus the danger of laceration of the bladder is said to increase, and mostly so shall such be the case in the presence of an alkaline urine, when phlebitis of the *plexus venosus prostaticus* might be followed by pyæmia It is only by an early and thorough asepsis, or antisepsis, with a proper drainage of the bladder during three or four days, that a thus endangered life may be saved

One of the main objections against the *lateral section* is based upon cutting the vas deferens and vesiculæ siminales of at least one if not both sides, followed by sterility If injuring these parts should really take place, then the danger will certainly be increased by performing the bilateral cut But the opinions upon that point are still divided, notwithstanding the many times that the operation has been performed

Secondary hæmorrhage, if it should happen, will mainly present itself with the patient coming out of the narcosis, when the bandages are removed and free motion of the limbs reestablished A sudden cessation of the flow of urine ought to be taken as an indication of either a second calculus, or coagulated blood Under all circumstances the surgeon must ascertain the real cause and convince himself that no other stone has been left behind

Epicystotomy, *Sectio Alta*, *Cystotomia Supra Pubica* —This method has also been highly recommended, especially in cases of children, on account of the peritoneum standing higher at that early age, than in later years, it being therefore out of the way to be wounded The operation has also been favored in presence of extremely large stones *Astley Cooper* and different other distinguished surgeons considered the operation associated with a great deal of danger, fearing not only of injuring the peritoneum but also of an infiltration of urine into the interstitial pelvic tissues, followed with suppuration, pyæmia, and frequently with death They place this method on an equal footing with the median operation, and a dangerous infiltration which might happen, induces them to doubt its superiority over the lateral section As if not under equal circumstances, as in presence of a decomposed, or, alkaline urine, the danger from infiltration would be as serious in the lateral section as in the sectio alta Since the objections raised against this operation cannot well be maintained, on the contrary, the method under circumstances, as in the presence of extremely large stones, or, their enclosure in diverticles of the bladder, may be desirable, whilst the comparative freedom from danger, if properly executed, will moreover enhance its value, I intend to give here such directions for its practical execution, as will render the method perfectly safe

I omit the initial steps of the operation, as cleaning of bowels, narcosis, position, etc , as sufficiently known The metallic bougie used here ought to have an inner slide, and should not be introduced before a deep narcosis has been obtained, an advice which holds good also in other methods where a bougie or catheter is to enter the bladder The best way to avoid injuring the peritoneum, consists in elevating the bladder by filling it to some extent with warm water, and likewise also the rectum after the narcosis has been effectuated Under an elongation of the urethra the bladder and plica Douglasii are raised, and sufficient room gained between the peritoneum and symphysis ossium pubis for the performance of the operation The plica peritonei hereby retires to the extent of three centimetres from the symphysis, so that a clean cut can be made into the bladder These three centimetres of the bladder are only covered by the fascia transversalis, which is recognizable and characterized by the fat enclosing that membrane even in lean persons, whilst it forms a thick layer in fatty persons Removing that portion of the fascia from the anterior wall of the bladder, instead of incising it, would be committing a great blunder *Rosir* has very properly warned against it

In performing, therefore, the operation of epicystotomy, and to secure success, the following steps have to be strictly and minutely executed After the catheter has been introduced, the bladder is nearly filled with warm phenol water, of 3 per cent , to retain which the catheter ought to be provided with a faucet The bladder in this manner being washed out three times with the phenol water before finally being filled, the catheter is removed and exchanged for the properly constructed bougie, with an inner slide Should the liquid escape at the sides of the instrument, an assistant has to compress the urethra around it The point of the bougie is pushed upwards right above the symphysis ossis pubis towards the anterior wall of the bladder An incision is now made in the linea alba between the pyramidales, in a downward direction, through the abdominal coverings, till the bladder has been reached When the point of the bougie is distinctly felt, two small hooks are inserted into the bladder on both sides of the point of the bougie and held there by assistants The bladder, with its covering fascia, is incised from the point of the bougie in a downward direction till the left index finger of the operator can be introduced, which finger then takes the place of the bougie, which is now retracted, the finger instead hooking up the bladder That finger is not to leave the bladder till the operation has been finished In opening the bladder some of the phenol water will of course escape, but having the bladder still secured by the hooks, a blunt-pointed bistouri is introduced, under the direction of the finger, and the bladder further incised downwards

The stone is now searched for, and when found, detached, and if not too large, it is easily grasped with the forceps, assisted by the finger, and extracted Should the calculus be inclosed in a diverticle, it has to be detached carefully In case of an extremely large calculus, the lithotriptor, or lithoclast of Luer, will be employed to crush the stone In order to obtain a larger opening, it has been proposed to cut the bladder in a transverse direction above the symphysis But herewith the inner pyramidales would be divided, causing a disposition to a subsequent abdominal hernia

In this method we have, therefore, the means of removing the largest as well as the smallest calculi

Time	*Centimetres*	*Cocaine applied*	*Remarks*
12 35	26		
"	26	2 per cent	
12 38	20		
12 40	18		Quick, short, pulsations
12 44		2 per cent	
12 50	16	2 per cent

In cases with extremely hard stones too hard for crushing with the common instruments, the bilateral section has been recommended, though others preferred the sectio alta, or even *recto cystotomy* Performing the bilateral operation the arteria transversalis is almost always, and the bulbo urethralis occasionally, cut I have seen the latter happen once, and a terrible bleeding to ensue, which the operating surgeon had the greatest difficulty in arresting The rectum in the cavum ischio-rectali is also considered

liable of being injured, and a fistula remaining here gave formerly a great deal of trouble in its cure With the increase in size of the calculus the danger of laceration of the bladder is said to increase, and mostly so shall such be the case in the presence of an alkaline urine, when phlebitis of the *plexus venosus prostaticus* might be followed by pyæmia It is only by an early and thorough asepsis, or antisepsis, with a proper drainage of the bladder during three or four days, that a thus endangered life may be saved

One of the main objections against the *lateral section* is based upon cutting the vas deferens and vesiculæ siminales of at least one if not both sides, followed by sterility If injuring these parts should really take place, then the danger will certainly be increased by performing the bilateral cut But the opinions upon that point are still divided, notwithstanding the many times that the operation has been performed

Secondary hæmorrhage, if it should happen, will mainly present itself with the patient coming out of the narcosis, when the bandages are removed and free motion of the limbs reestablished A sudden cessation of the flow of urine ought to be taken as an indication of either a second calculus, or coagulated blood Under all circumstances the surgeon must ascertain the real cause and convince himself that no other stone has been left behind

Epicystotomy, Sectio Alta, Cystotomia Supra Pubica —This method has also been highly recommended, especially in cases of children, on account of the peritoneum standing higher at that early age, than in later years, it being therefore out of the way to be wounded The operation has also been favored in presence of extremely large stones *Astley Cooper* and different other distinguished surgeons considered the operation associated with a great deal of danger, fearing not only of injuring the peritoneum but also of an infiltration of urine into the interstitial pelvic tissues, followed with suppuration, pyæmia, and frequently with death They place this method on an equal footing with the median operation, and a dangerous infiltration which might happen, induces them to doubt its superiority over the lateral section As if not under equal circumstances, as in presence of a decomposed, or, alkaline urine, the danger from infiltration would be as serious in the lateral section as in the sectio alta Since the objections raised against this operation cannot well be maintained, on the contrary, the method under circumstances, as in the presence of extremely large stones, or, their enclosure in diverticles of the bladder, may be desirable, whilst the comparative freedom from danger, if properly executed, will moreover enhance its value, I intend to give here such directions for its practical execution, as will render the method perfectly safe

I omit the initial steps of the operation, as cleaning of bowels, narcosis, position, etc , as sufficiently known The metallic bougie used here ought to have an inner slide, and should not be introduced before a deep narcosis has been obtained, an advice which holds good also in other methods where a bougie or catheter is to enter the bladder The best way to avoid injuring the peritoneum, consists in elevating the bladder by filling it to some extent with warm water, and likewise also the rectum after the narcosis has been effectuated Under an elongation of the urethra the bladder and plica Douglasii are raised, and sufficient room gained between the peritoneum and symphysis ossium pubis for the performance of the operation The plica peritonei hereby retires to the extent of three centimetres from the symphysis, so that a clean cut can be made into the bladder These three centimetres of the bladder are only covered by the fascia transversalis, which is recognizable and characterized by the fat enclosing that membrane even in lean persons, whilst it forms a thick layer in fatty persons Removing that portion of the fascia from the anterior wall of the bladder, instead of incising it, would be committing a great blunder *Rosir* has very properly warned against it

In performing, therefore, the operation of epicystotomy, and to secure success, the following steps have to be strictly and minutely executed After the catheter has been introduced, the bladder is nearly filled with warm phenol water, of 3 per cent , to retain which the catheter ought to be provided with a faucet The bladder in this manner being washed out three times with the phenol water before finally being filled, the catheter is removed and exchanged for the properly constructed bougie, with an inner slide Should the liquid escape at the sides of the instrument, an assistant has to compress the urethra around it The point of the bougie is pushed upwards right above the symphysis ossis pubis towards the anterior wall of the bladder An incision is now made in the linea alba between the pyramidales, in a downward direction, through the abdominal coverings, till the bladder has been reached When the point of the bougie is distinctly felt, two small hooks are inserted into the bladder on both sides of the point of the bougie and held there by assistants The bladder, with its covering fascia, is incised from the point of the bougie in a downward direction till the left index finger of the operator can be introduced, which finger then takes the place of the bougie, which is now retracted, the finger instead hooking up the bladder That finger is not to leave the bladder till the operation has been finished In opening the bladder some of the phenol water will of course escape, but having the bladder still secured by the hooks, a blunt-pointed bistouri is introduced, under the direction of the finger, and the bladder further incised downwards

The stone is now searched for, and when found, detached, and if not too large, it is easily grasped with the forceps, assisted by the finger, and extracted Should the calculus be inclosed in a diverticle, it has to be detached carefully In case of an extremely large calculus, the lithotriptor, or lithoclast of Luer, will be employed to crush the stone In order to obtain a larger opening, it has been proposed to cut the bladder in a transverse direction above the symphysis But herewith the inner pyramidales would be divided, causing a disposition to a subsequent abdominal hernia

In this method we have, therefore, the means of removing the largest as well as the smallest calculi with comparatively little difficulty. Nevertheless, in case of a catarrh, or of other complications of the bladder, as a cystitis or pyelonephritis, with a decomposed urine, and where drains have to be applied, the propriety of performing the operation of epicystotomy may well be questioned. The necessity of keeping the bladder empty would expose the patient for some time to the most uncomfortable abdominal position (though such has been recommended).

In the presence of a very extensive middle lobe of the prostate, when *posterior catheterism* should become necessary, or even external urethrotomy be required under such circumstances the method would certainly have no superiority over the pærenial median of Allarton, since the bladder has to be kept in a constant aseptic condition. In uncomplicated cases, with an acid urine, where no interstitial infiltration need be feared, the wound could be farther attended to.

Here it has been recommended to sew up first the bladder, and in applying the sutures very close to each other, to facilitate "a healing by first intention." In thus sewing up the wound, the sutura nodosa with well carbolized silk, ought to be applied, but taking care not to enclose the mucosa in the sutures. If by filling the bladder now with phenol water, it be found water tight, then the abdominal coverings, such as skin, muscles and fascia, may all at once be enclosed in that second row of sutures. But a successful healing of the wound of the bladder by first intention being so difficult to obtain, since it requires a very accurate application of the wound's edges, the latter is better left to heal by granulation, under an exact appliance of an aseptic occlusive dressing. In such a dressing the scrotum and the upper part of the thighs ought to be encompassed, leaving out only the catheter in the urethral canal for injecting the bladder three or four times daily with three per cent. phenol, or, thymol water.

In case of a calculus being enclosed in a diverticle, it is alone the Sauverdin method by which the exhæresis of the stone can be accomplished without any laceration of the bladder. The operation further leaves no incontinence of the urine, neither is a subsequent sterility to be feared. The bleeding is but a minimal one. A hypertrophy of the prostate is irrelevant and in strictures of the urethra, be they spasmodic, or impenetrable, there is certainly next to Allarton's method no better operation recommendable.

There is left for me one more operation belonging to this division, to say a few words about the

Procto Cystotomy.—Cystotomia recto vesicalis.—Of some eighty reported cases up to the year 1881, the mortality has been 1 in 5.3. If more were required to assign that method its proper place in surgical practice, it might be mentioned that the ever practical Malgaigne, in the latest edition of his "Operative Medicine," has totally relegated that operation from its contents. That ought to be sufficient for its condemnation, nevertheless, let us see if something could not be said in its favor, the more so since it was once held in especial appreciation by that distinguished Italian surgeon, Vacca Berlinghieri, who favored it on account of its easy execution and being an almost bloodless operation. My friend L. Bauer, of St. Louis, formerly of Brooklyn, N. Y., who performed that operation in 1859 successfully and for the first time, as he said, that the operation had been performed in this country, also claimed for it a superiority over all other methods. Bauer was no doubt led to that opinion like Berlinghieri, by its easy execution and successful issue, but such are not the only, nor the most important factors, in assigning a method its proper place in surgical practice.

If we distribute the rectum according to the anatomist Hyrtl, into three sections, then the second or middle section will extend backward alongside the os coccygis and sacrum, and in front from the prostate till to the plica peritonei, or, Douglasii. Its length is variable. With an empty bladder it measures from 5 to 7 ctm. (2"–2½"). If the bladder is extended by being filled with water, it takes hold of the plica Douglasii, or, that place where the peritoneum coming from over the fundus of the bladder is attached to the rectum. It will be moved somewhat higher up and correspond with the concavity of the sacrum. The total length of that section in its anterior portion is in contact with the fundus of the bladder, while at its sides the seminal vessels are met with. The easy injury of the latter by the recto vesical cut and perhaps a deep position of the plica Douglasii, whereby the peritoneum may be injured, was the cause that one of the former defenders of that method, Sanson, again relinquished it. It is moreover an undeniable fact, that in elderly people the peritoneal duplicature of the rectum descends further down than commonly, and that in large stones the incision, if extended too far upwards, may come in contact with that membrane and even open the abdominal cavity, to say nothing of cutting the seminal vessels and causing sterility. Another salient point in its disfavor, consists in the inability of the surgeon to apply a proper aseptic dressing, nor is it always in his power to protect the wound against a sudden descent of fœcal matter. A remaining recto-vesical fistule, which has also been mentioned among the objections, has to day lost its importance, since its cure, or failure of being cured, depends exclusively upon the skill and dexterity of the surgeon. Regarding the material used here for sutures, it does not matter whether silver, annealed iron wire, or carbolized silk is used. It was a mistake that I, with many others in this country once committed, to think that metal wire possessed a special virtue. It was an error, since properly prepared carbolized silk will serve the same purpose as wire, and "the new and lasting impulse in lithotomy" which Bauer ventured to predict upon the potency of silver wire sutures has not only not been verified, but they were not even able to save the operation in question from being thrown into the waste basket. Even in modifying the operation, by placing the highest point of the incision not further up in the rectum than about 2½–3 ctm., altering thereby the cystotomy into an urethrotomy, securing the peritoneum against any possible injuries, even then would the impossibility of applying an aseptic dressing be sufficient to doom the method. In complicated cases in the presence of a cystitis, of an alkaline, or decomposed urine, when the wound must remain open and a healing of it per primam could not be thought of, the constant exposure of the wound to being contaminated with fœcal matter, not to speak, moreover, of the interstitial infiltration of the urine and its life endangering consequences, would offer sufficient reasons to relinquish the operation, even in its modified form.

Calculus in the Female Bladder.—Calculi in the female bladder are also of renal as well as of vesical origin. The interior of some of these stones is either oxalates or urates, while its greater portion, the covering, consists of phosphates. It also happens that the nucleus may be a foreign body, such as a hairpin, a straw, etc., which in most instances found their way into the bladder through the urethra, as in children playing with such substances. In one case that of a young lady, a hairpin which had been swallowed accidentally, nine years previously, and which finally became located in the bladder, and in part incrustated, was extracted with a dressing forceps.

The singular incident that calculi in females have been and are still occasionally overlooked, may find its explanation in a careless examination, but also by the fact that uterine disorders frequently accompany an excitability of the bladder, and it thus happens that such calculi are at first taken and treated for uterine disorders. In all such obscure cases a thorough examination of the bladder ought never to be overlooked, and this is best executed by the finger of one hand in the rectum, whilst the other hand carries the bougie, or presses deep into the abdominal coverings above the symphysis pubis.

The removal of a calculus from the female bladder, if not executed through the artificially, gradually dilated urethra, either entire or after having been crushed by lithotriptic instruments, is best accomplished in cutting through the anterior vesico-vaginal partition wall, a method formerly much feared on account of a remaining fistula, for a long time considered one of the approbria in surgery, and, singular to say, from the mere failure of a properly constructed speculum by which the parts could be made more accessible to the operator. And what is still more singular, when that speculum had been finally discovered, in Germany, and its description was accompanied by six successive cures of vesico vaginal fistules by the German Metzler, it was overlooked till it came back from the new world to the land of its invention under another name, and encumbered with some paradoxical paraphernalia fully documental of its real origin. The silver-wire sutures, divested at a later date of their imaginary attributes, were replaced by carbolized silk, without altering the success of the operations. Vesico-vaginal fistulas are to day no longer feared, and their cure may be predicted with an absolute certainty.

In order to examine the interior of the bladder with the finger, in case a caculus is enclosed in a diverticle of the bladder, in "*a vessie a colones,*" the late Professor P. Simon, of Heidelberg, Germany, invented a set of specula made of hard rubber, and secured with a conical obturator or mandrin. These specula, of seven different sizes, from nine to nineteen mm. in diameter, he introduced one after the other, and became thus enabled to dilate the urethra to a lumen of two centimeters, after having incised previously the mucous membrane of the meatus urinarius by slight cuts of one-quarter to one-half centimeter deep, in four opposite directions, to avoid its laceration. Notwithstanding these forced dilatations at so short intervals, Simon never saw either a paralysis or an enuresis follow, the urine being always retained. In this manner a palpation, or illumination of the interior of the bladder could be executed, not merely in case of stone, but also in other diseases, like hypertrophy or tumors of the bladder. As a matter of course, these dilatations must only be made when the patient is in deep narcosis, to avoid the pain, as well as the spasmodic contractions of the sphincter vesicæ and the muscular fibres of the urethra.

I will here add a chapter of great importance to the surgeon, not merely on account of its intrinsic value, its relation to the parts which hereafter come into question, but also on account of the many existing errors committed by diverse authors. It is the *topographical anatomy of the pelvis minor.*

The existing errors and confusions in the description of these parts of the human body, comprising the pærineal region, and the interest every surgeon must feel for a correct information, induces me to write this chapter, and the more so since I have dissected these parts more than once, and in part as specimens for the anatomical museum of the University of Marburg. Seldom did I meet with a truer description than that given by the great anatomist, Hyrtl.

Well says the Nestor of anatomists: "The pærineum in the pen of authors has become a true Proteus, producing a mess which it is difficult to unravel." Considered externally, we find the pærineum limited by the root of the scrotum, the anus and the tubera ischéi, or those furrows caused by the thighs. The arcus ossium pubis is the skeleton of this region. The pærineum has three aponeuroses, or fasciæ pærinei. Its upper aponeurosis is situated underneath the subcutaneous cellular tissue, and ought to be named *fascia pærinei superficialis.* It is nowhere attached to the skeleton, though Quain, says Hyrtl, inserts it at the arcus ossium pubis. This aponeurosis comprises merely some indifferent blood-vessels and nerves, and is without any surgical importance.

The next or middle aponeurosis is the *fascia pærinei propria.* It is attached posteriorly to the levator-ani, os coccygis, and the tubera ischei, anteriorly to the arcus ossium pubis. Being strongest in its forepart, it is perforated by the pars membranacea urethræ of 20 to 25 mm. in length, behind it is perforated by the rectum.

The lower aponeurosis, which is commonly named the *fascia pelvis*, forms the basis of the pelvis minor, and is perforated by the organs passing through the pelvis. It is united with the levator ani. The anterior portion surrounds the neck of the bladder and prostate, as the ligamentum pubo-vesicale and prostaticum, originating at the posterior part of the symphysis pubis   Another portion of it, attached to the tubera ischei, forms the ligamentum ischio-prostaticum

The last one, coming from the sides of the smaller pelvis, is the largest and most complicated one, and is known as *processus falciformis*   It has two layers, the inferior, which goes to the bladder and to the anterior portion of the rectum, and is called fascia recto-vesicalis   The strongest portion of this aponeurosis is adherent to the prostate and to the fundamentum vesicæ   The superior layer is covered by the peritoneum, which is connected with it by a loose cellular tissue   Above this aponeurosis the cystotome ought never to be entered   In cutting into the raphe of the pærineum, in order to open the membranous portion of the urethra, we will have to divide the anatomical layers in the following order   *cutis, subcutaneous cellular tissue, panniculus adiposus, fascia pærinei superficialis, plexus venosus* (inferior hemorrhoidal veins), *pars membranacea*, or, *isthmus urethræ, surrounded by Guthrie's and Wilson's muscles* (*musculi pubo urethrales*)

So much for this concise classical description of Hyrtl, of the correct anatomy of those parts of so important an interest to the practical surgeon

The Urethra —In the previous chapters it occasionally happened that further explanation of a subject was promised subsequently   If under this and the following headings, therefore, some repetitions should occur, I hope they will be excused as unavoidable

A very important element in the nature of the urethra is its dilatation, its expansion   A healthy urethra, as stated by Dr Otis, one of the distinguished American surgeons (and also present at the International Medical Congress) has stated the caliber of the urethra to be about 32 mm , whilst its meatus is given to be 24 mm in circumference   Bigelow employed usually a catheter of 29 mm (18 mm engl), which means the caliber of a well-extended urethra   Otis further stated that if the flaccid penis, *i e* , its pendulous portion measured 75 mm (= 3" engl) in circumference, the urethra would have a capacity of 32 mm , and so on , so that 6¼ mm (or ¼") increase of circumference of the penis at or about the middle of the pendulous portion, would indicate an increase in size of the urethra of 2 mm   The range of the normal urethra, as demonstrated by measurements (done by Otis with his urethrometer), in several thousand cases has been given from 28 to 45 mm in circumference, while the normal caliber of the urethra, as claimed by surgeons of all parts of the world, did not formerly exceed 21 mm in circumference   In England and America, till Otis undertook these measurements with his urethrometer, the caliber of the urethra was accepted to be from 17 to 18 mm , and in France 21 mm   In one hundred carefully measured cases Otis received, in the average, 31 84 mm when more or less strictures had been present, and 32 93 mm in urethra supposed healthy   It will thus be seen that much larger instruments may be used in passing them through the urethra, as in lithotripsy, without fear of a rupture of its mucous membrane, than has been heretofore supposed

Otis has given comparative normal measurements, but they, of course, do not indicate the maximum of dilatation which the urethra may undergo under certain circumstances, as for instance, under a gradual extending power and when a further portion of the urethra has been incised near the opening of that organ through which an entrance into the bladder is forced, or through which a stone is to be removed   That this is the main and most important question in performing the pærineal median operation of Allarton, or urethro-lithotripsy is self-evident   From my statements and measurements given in the case operated upon with Allarton's method of the stone, including the forceps, which both together had passed through that part of the urethra from the neck of the bladder to the beginning of the incision, without causing the least laceration, the circumference of the extended urethra measured 88 mm , instead of the circumference of a normal urethra after Otis from 28 to 45 mm , or of a hundred carefully measured cases in the average from 31 84 to 32 95 mm in more or less healthy urethras   The extension of the urethra in my case, large as it appears to be, certainly does not prove the utmost dilatation of that organ, since not even a sign of blood became visible on the finger, introduced after the extraction of the calculus

The above-mentioned measurements of Otis were given by him at the International Congress, and from what I have stated here, we can understand the success of Bigelow's method with his large lithotriptor and evacuating sound

Previous to beginning the operation of external urethrotomy it is necessary to make a thorough examination of the urethra, as well as of the instruments   About 8–10½ ctm or 3–4 inches from the meatus urinarius, what Otis calls the peno scrotal angle (the beginning of the pars pendula penis), we meet frequently, after Otis, small bands   These bands, as well as all other localized constrictions of the urethra, from whatever cause, ought to be removed, either by a gradual dilatation, or internal cutting, so the instruments shall not be clogged, says Otis   The meatus, when much narrower than the balance of the urethra, has first to be widened by small cuts through the mucous membrane, as already mentioned   But all of these precautions and actions are of value only in a subsequent lithotriptic operation, whilst they are indifferent to either urethrotomy, or urethro-lithotripsy with an incision beyond those bands or localized constrictions

Construction of the Catheter —I consider it a fit place to call attention here to a new form of catheter which the late Prof Hueter recommended as based upon the anatomical structure of the urethra

Hueter, by whose recent and quite unexpected death surgery has suffered a heavy and irreparable loss at our time, called attention in his monumental work on surgery (one of the best if not *the* best work on surgery at present in existence, and with which he has set himself a most brilliant and imperishable epitaph), I say Hueter called attention to the efficiency of Stearn's instrument for the dilatation of strictures of the urethra (Stearn's dilator is an American invention) The fact that he could pass that instrument, consisting, as known, of two movable flattened wires, through strictures through which he could not pass a round instrument of the form of our common metallic bougies or catheters, and of the same diameter, induced Hueter next to have given his catheters a similar elliptical form, and he had the satisfaction to experience the great benefit thus derived from that modification But Hueter soon after also discovered the theoretical reason for this serviceable alteration When the urethra of a dead subject is filled from out of the bladder with a paste of gypsum, and after the paste has hardened and the soft parts have decayed, a proper impression is obtained of the form of the urethral tract, the normal anatomical construction of the urethra, thus obtained, of the part corresponding to the glans penis presents a perpendicular cut, while the balance from the fossa navicularis backwards including the pars cavernosa, membranacea and bulbosa, are transformed into a horizontal split, in which the upper urethral wall lies attached in close contact to the lower one The middle part of the urethra, which is widest, will permit the passage of a common round bougie as well as of one flattened or oval, but towards the pars membranacea the channel obtains more the form of a reclining oval

In the handbook of Billroth and Pitha (Bd III 2d div , 8 part, page 41) Socin has given the urethral split in the form of an inverted T (⊥) Hueter's oval male catheters have two eyes near the point, one at the convex, the other on the concave side of the curvature The entrance to the channel of the catheter is the same as on the common round one That the new form is easier of introduction and causes less irritation has been observed by all persons who have tried both forms upon themselves The great facility and disencumbrance of introduction was surprising to all of the old habitués using the catheter "But there is even a time for the specialist, when the urethræ of the patients have to pay for the apprenticeship," says Hueter "The number of these sufferers would certainly be diminished with the use of the oval catheter " Even in the swelling of the prostate, which is the most fruitful cause for a punctio vesicæ in retention of urine, this form of the catheter might be of great service in reducing the mortality from that operation, which according to a careful collection has been given at 13 per cent Hueter asserts that in such a swelling of the prostate, his oval catheter would enter easily, when the round one would not enter at all, displacing the middle lobe of the gland to make room for the instrument to enter the bladder, by adapting itself better to the small horizontal split, thereby preventing its point from entering the tissue of the gland and causing "false passages "

During 32 years of professional practice in this city, I have been obliged but twice to perform puncture of the bladder, among dozens of cases of retention of urine, from an extensive increase of the middle lobe of the prostate Both cases recovered, though they happened in the beginning of my practice and when no aseptic treatment was thought of I was also present when a surgeon, by pushing the trocar through the rectum, not only failed to enter the bladder, but, singular to say, postponed a second attempt for the next day (!), when he had the misfortune of meeting with a corpse The man, colored, about 55 years old, died during the night of violent peritonitis At a later period, after I had become acquainted with the wonderful efficiency of the galvanic current in the treatment of strictures and obstructions caused by an hypertrophied prostate, it never happened to me again to have recourse to the forcible and rude means of the use of the trocar in similar conditions, but always succeeded with patience and the use of the proper pole of the battery attached to the bougie or catheter, to enter the bladder

[TO BE CONTINUED]

DELIRIUM TREMENS

BY JAMES T WHITTAKER, A M , M D

Professor of the Theory and Practice of Medicine and Clinical Medicine, Medical College of Ohio

A Clinical Lecture Delivered at the Good Samaritan Hospital, Cincinnati, December 1 1884

[*Reported by James M French, M D , Assistant to the Chair*]

GENTLEMEN—The resident physician, Dr Carter, will read us the history of the case

"*History*—Thomas D , æt 48, a laborer, has been a hard drinker for twenty-seven years For a period of five or six years just preceding the present year, he abstained from drink, but during the year just past he has indulged very freeely He has had two attacks of delirium tremens—the first in 1861, the second in 1865 During the first attack he says that he imagined he was lying in a bed of serpents, and that the room seemed to be filled with demons of the most fantastic shapes At an unguarded moment he ran from the house, pursued, as he imagined, by a huge snake that seemed to crawl through his clothing, and was endowed with articulate speech The patient was admitted two days ago, and stated that he had had an attack the previous night In the attack his room seemed to be filled with various animals, as dogs, cats, rats, birds and insects, which sported about and seemed to get into his bed, and crawled about his person Yet he was able to cause them to disappear by kicking them off He also saw figures of gigantic men, who appeared about to fall upon him He heard, too, numerous voices reproaching him, so that he was unable to sleep His mouth, he thought, was filled with grass, which he could not get out, and with the grass he thought he was trying to spit out devils During the day of his admission he was pretty quiet, and he rested pretty well the following night Yesterday, however, he could not be restrained, but wandered about the ward in an indifferent, abstracted mood, appearing unconscious of his movements So marked was this that while he was standing before the fire the sheet in which he was wrapped became ignited, and was torn from him without arousing his attention. After this accident he was secured in bed. Toward evening he fell asleep, and rested quietly all night and the greater part of this morning. His appetite has been ravenous, almost insatiable during the course of his illness. At present he is fully conscious of all his actions and surroundings."

I asked the resident physician in preparing the history that he has just read to record just what the patient said, and he has given us a very succinct account of the delusions which are common in these cases. I wish you could have seen the patient in the height of the attack, for you would then have seen a picture that you would never have forgotten. Now he lies quiescent, and is not affected even with tremor; there is no tremor of the hand or of the tongue. Nevertheless, I think it is perfectly plain to you that we have had to deal with a case of delirium tremens. It is generally pretty easy to recognize one of these cases, but every now and then a grievous mistake is made. Not infrequently an individual is picked up on the street, and perhaps carried to the station-house, thought to be suffering from delirium tremens, and it turns out afterwards that he has had a sunstroke, is apoplectic or uræmic, or has received a blow upon the head. Only a few years ago a man was found propped up in a door way in this city, like the hunchback in the story. He was carried to the station, and died in a short time. When the body was examined the next morning, it was found that the individual had been shot through the brain.

Then a man may have delirium tremens that is not due to the excessive use of alcohol. A man may show delirium and a tremulousness that is characteristic of the disease before us, in any acute infection, especially in typhoid fever and in septicæmia. Neither does alcohol give every man delirium tremens, or the affection would be a great deal more common than it is. It comes on, as a rule, after or in the height of a debauch. This man has been a hard drinker for a great many years, but this is only the third attack he has had. I have no doubt that he has been found in a condition of acute alcoholic prostration a number of times, but that is a quite different condition from delirium tremens. The effect which we here observe is produced by the direct action of the alcohol on the brain. In all cases, in fact, alcohol expends its force upon the brain; first upon the great brain, then upon the centres of motion at the base, then upon the cerebellum. The centres of respiration are last but most profoundly affected, and when a man dies from alcoholic poisoning, he dies of apnœa. He literally chokes to death. We see this from the cyanosis, from the suffusion of the face and surface. Often we are called upon to decide whether a man has acute alcoholic coma, uræmic or apoplectic coma, or is suffering from an injury to the brain. So it behooves you well to know the signs of delirium tremens.

Perhaps you know that it is a disease that is not so common in some countries as in others. It is most common in cold climates, as in Norway, Sweden and Denmark, because in these northern countries there is a constant craving for stimulating drink, not felt so much in warmer climates. In cold climates the tissues are consumed more quickly, and this accounts for the constant craving for alcohol. In warm climates, where wine and beer flow like milk and honey in the Promised Land, you will scarcely meet a case of delirium tremens. In these drinks the alcohol is in much less amount. Brandy has 60 and wine and beer but 2 to 6 per cent. of alcohol.

Thomas Sutton, an English physician, was the first to give a distinct description of this disease. He taught us that there are three characteristic symptoms to be looked for, namely: delirium, tremor and insomnia. So it is sometimes said that delirium tremens is a disease which stands upon a tripod. There should be added a fourth symptom, a symptom which, however, is rather a negative than a positive sign. Delirium tremens is not accompanied by fever. When we find all these four symptoms present, delirium, tremor, insomnia and apyrexia we can have no doubt of the character of the case.

For the most part an individual who is attacked with delirium tremens has it come upon him suddenly. Not infrequently it is prefaced by or associated with nausea, vomiting, anorexia, etc., then the individual becomes delirious. You heard all the phenomena of the delirium in the history read by the resident physician. The individual sees curious objects, and all kinds of animals, strange to zoology and comparative anatomy, serpents and dragons, such as might be read of in the "Arabian Nights" or fairy tales. He tells us now that he was in his earlier attacks, pursued by snakes. I doubt very much whether he really saw snakes at all when he was in the delirium. It is more usual for these individuals to see insects, small animals as mice, rats, beetles and bugs, that crawl all about them, fill the room and for the matter of that all inter-planetary space. Or they may see objects about them transformed into objects of horror. The bed-posts become transformed into huge dragons, and a chair is changed into a demon. More especially the patient fears his fellows. Assassins, he imagines, are standing at his door or crouching under his bed waiting to kill him. He jumps out of bed and in his alarm, perhaps, escapes from the house. I have known a physician going through a ward with a stethoscope in his hand, beaming with benignity, to be mistaken by one of these patients, for a robber or a murderer, the stethoscope mistaken for a weapon, and the patient jump from the bed and run for his life. These individuals are not permitted to rest by reason of their perverted fancies. They are just about to fall into a sleep when they are awakened suddenly with a start, a shudder, or a shriek at the demons which have been meanwhile conjured up. It is not that the patient wants to injure any one, it is fear that characterizes his attack. The physician and attendants are mistaken by him for assassins, and from these he desires to escape. It is not, as a rule, I say, a maniacal onslaught that they make, but everything with them is the attempt to escape from danger. This is the characteristic of delirium tremens, horror and fright and fear. You see the expression of terror in the dilated pupil, in the general physiognomy that is unmistakable.

After or with the stage of delirium, comes the tremor; tremor of the hands, of the tongue, of the jaws, and agitation of the extremities. The tremor of the hands is more marked than in paralysis agitans. It is a tremor, too, that is manifested when the individual is quiescent. This man can now hold his extended hand quiet as you see, but even for a long time after the individual has recovered, volitional movements are marked by feebleness and tremor. The tremor also affects the tongue, so that the individual has difficulty in speaking; he disarticulates his words. You ask him to put out his tongue, and it is with difficulty that he obeys you. Tremor is, in in fact, a symptom so prominent and so persistent that it has baptized the disease with its name.

Another of the more important symptoms is sleeplessness. The individual would fall into sleep from exhaustion, were it not for the fact that he is constantly aroused by his fears. If he falls asleep, he awakes, as I have said, with a start or a shudder. Again he falls asleep, but only to be again awakened with a start, and to see the room filled with objects of terror. To what extent this insomnia destroys the rest of the patient, you can learn from the enormous doses of hypnotics we have to administer in order to give him rest. We often have to give doses that compel us to stand by the bed-side and watch the patient until the action of the remedy has to some extent worn away. Thus we sometimes incur the superadded danger of narcosis in our attempt to give the patient sleep.

You take the temperature in a doubtful case and you find that it is normal, or if you take it as the full action of the alcohol has expended itself, you may find it slightly below the normal. You know that alcohol reduces temperature. We give it now in preference to quinine in septic diseases, because it reduces the temperature absolutely. Typhoid fever shows us a fever during the stage of delirium, and this you would also find in the history of septicæmia. There might be times in the course of a septicæmia when the temperature would be normal or subnormal, but as a rule you would find it elevated. You would also have in the history, the statement that the patient had had a chill or a succession of chills, so that you would have no difficulty in the diagnosis. You can not produce alcoholic intoxication in a case of sepsis. When alcoholism supervenes the disease, as a rule, is done. There are other points of great value in the diagnosis. In the first place the gastric distress sometimes enables you to make a diagnosis at once. You find that the individual's clothes are soiled, or the ground near where he lies is covered with vomited matter. You investigate the vomited matter; don't be afraid to put your nose down into the vicinity of it, and you detect the odor of alcohol, or rather of the etherial oils that accompany the alcohol. You put your head down close to the individual and you discover the odor of alcohol in his breath.

Another thing. These patients are brought by alcohol into a state of anæsthesia. Alcohol produces anæsthesia. In the days before the use of chloroform and ether, the surgeons, when about to operate, gave the patient a drink of whisky, and even now, in trivial operations, where it is not considered necessary to administer an anæsthetic, we give the patient a glass of good wine or whisky, and a kind of anæsthesia is produced. In delirium tremens this anæsthesia is plain enough. The patient who has jumped from a window to the ground gets up and tries to walk away with a cracked pelvis or a broken limb, unconscious of any injury.

We have now had signs sufficient in a diagnostic way to distinguish this disease from others that may simulate it. The delirium, the tremor, the gastric distress, the insomnia, the absence of fever and the anæsthesia distinguish it enough. Generally, however, the individual comes to you with the history of delirium tremens. He has, as a rule, been a continual drinker. The attack you see is not the first.

It is only a certain percentage of persons, as I have said, that have delirium tremens; and these persons are often victims of other neuroses. It is surprising how often epilepsy is associated with this disease. Westphal has shown us that 30 per cent. of these cases are epileptic before the disease comes on, and 30 per cent. are seized with epilepsy after it.

But there is no rule without exceptions. I have intimated to you that delirium tremens is a disease without fever. Now, fever is sometimes associated with it; but when this occurs the elevation of temperature does not belong to the delirium tremens proper; the fever is due to complications that are accompanied with fever. Perhaps the most common complication of delirium tremens is pneumonia. This is due, to a great extent, to the exposure to which drunkards are subjected. The individual, in many cases, has fallen into a gutter, and has got wet, and a pneumonia supervenes. The pneumonia of drunkards is frequently a double pneumonia, and there is no pneumonia that is so fatal as a pneumonia during alcoholism—not only because it is so often double, but because the man's bad habits have broken him down, and destroyed his powers of resistance to disease. Next in frequency to a pneumonia is a pleurisy; but a pleurisy runs, as a rule, a much more favorable course. What you will learn to watch for with much greater interest is a meningitis. This is the complication that makes the individual the victim of maniacal delirium. You would observe, in a case of this kind, fever, and a contracted condition of the pupils, instead of the dilatation that is usual in these cases. Above all things you would lay stress upon the fever. Now, because a man has a maniacal delirium it does not imply that he has a meningitis, for an individual generally has maniacal disturbances in the excitement of his fear some time in the course of the disease. It is occasionally very difficult to restrain these cases of delirium. In the hospitals where they treat a great many such cases they have padded rooms, where the individual can pitch around as much as he likes without injuring himself; but here we have to use restraint, and sometimes it is necessary to put on the straight jacket, on account of extreme violence.

Westphal has shown that six per cent of these cases attempt suicide, but homicide is almost unknown. When it does occur, it is accidental, in the effort to escape. This man, we are told, wandered around the ward until he set himself on fire at the grate, and so profound was the anæsthesia that he paid no attention to the accident at all.

Suppose, now, that you should see an individual lying in the street in an acute state of intoxication, or coma, and it should become a question to what the coma was due, how would you decide? Well, in an attack of opium poisoning, you would notice the pupils contracted down sometimes to a pin-point, but you must remember that when the stage of asphyxia comes on in opium, they sometimes dilate. Next you would have the respiration reduced probably to only four or six per minute. This slow respiration is characteristic of both affections, because both poisons affect the medulla, but it is more marked when due to opium. Thus, with the pulse, pupils and respiration, you would draw a line between alcohol and opium, especially if you could get anything of the history of the case, or if you could detect an odor of either drug upon the individual. If you suspected uremia, you would at once draw some urine from the bladder and examine it for albumen. But many drunkards have albuminuria, and in such a case you could not distinguish the affection. As a rule, however, this complication does not cause any difficulty, and you could eliminate one or the other. Look for the dropsy of Bright's disease, especially under the eyes. As for injuries about the head, you would have to examine the head, of course. Most mistakes are made where the physician has taken it for granted that the case is one of alcoholic intoxication without examining properly. I know of nothing more humiliating to the physician than to make a mistake like this.

What will you do for a case of delirium tremens? I have already intimated to you that it is not, as a rule, a dangerous disease. Most cases recover. When they die, they die of complications, or those slow changes that are brought about by the continued ingestion of alcohol, namely, the destructive inflammation of the connective tissue of the brain, giving rise to progressive paralysis of the insane, or a chronic inflammation of the connective tissue of the liver, giving rise to cirrhosis. I have told you that it is necessary to use some restraint in these cases. Now you should use just enough force to keep the patient quiet, and not any more. If you have attendants enough, it is only necessary for them to watch beside the bed and to keep him from leaving it. It is more a matter of vigilance than of force. But that cannot be done, as a rule, because these are generally men who have run through with their fortunes and cannot hire attendants enough.

We have next to discuss remedial agents. The best remedy is chloral, but to have success, we must give it in large doses. It is better to give it in one large dose, as forty grains at a time, than in repeated small doses. Chloral is preferred to other remedies because it does not interfere with digestion and does not leave any traces behind. But then there are certain contra-indications to its use. You could not give an old drinker chloral; the alcohol has already produced changes in the heart that you must watch. The heart has become fatty, and the aorta atheromatous. You detect these changes in the pulse or by putting the ear down over the heart. Many and many a drinker has been pushed off with a dose of chloral. What then, in a case in which you could not give chloral, would be the substitutes? The best substitute is opium. Opium was looked upon as the sheet-anchor in these cases until the discovery of chloral. You shall give it in the form of morphia in the dose of quarter or half a grain under the skin that it be not rejected, and watch the effects. The individual as a rule falls of into a sound sleep, but you would hesitate to give the remedy too frequently. You may have to repeat the dose once or twice until the patient gets a grain or more, but you would watch the effect closely; you would watch to see if the pupils were contracted. If dangerous symptoms supervened, you would have to sit down beside the bed and keep the individual awake. You do not have to make him walk about to do that, but simply sit beside him and occasionally pinch his ear or slap his face or especially call him by name; usually this is enough. While you watch the patient count his respirations. As a rule you would not venture to leave him until his respirations were as frequent at least as ten per minute. Do not forget how boldly you may use atropia, in the dose of half a grain hypodermically, in a desperate case. Now, in a case where there was some sign of fatty degeneration of the heart, as there is in the case before us, you would certainly put the patient under digitalis. Grade your dose according to the condition of the patient; sometimes you will have to give as high as a tablespoonful of the infusion every two hours. Then there is a remedy which you would have the patient use as a drink, and it is in a mild case almost a specific, namely, coffee; you would have the individual drink strong coffee. Let him drink it without any milk, because the tannic acid of the coffee coagulates the albumen of the milk, and renders it less easily absorbed; or you might give the active principle of coffee, caffeine.

Binz found that coffee was an absolute antidote to alcohol, and that dogs saturated with caffeine could hardly be intoxicated with alcohol. So you would use coffee or caffeine, and you would recover your patient, as we have done this man within the short space of twenty four hours. Lastly, if you choose, when you are all through you may lay aside the role of physician and assume that of the preacher. You can generally do more good than the temperance lecturers. You can call attention to the harm that alcohol does to his brain and his liver. These are the chief organs to suffer; but you are not hence to infer the alcohol is carried irregularly over the body, it is carried uniformly everywhere—absorbed always by the veins—never by the lymph vessels. Tell your patient that alcohol is one of those poisons that leave a permanent effect. Opium does not, and nicotine does not. A man may suffer the profoundest poisoning with opium and nicotine, and yet recover entirely from it A man may take either for years, but the moment he stops the poison is eliminated But it is not so with alcohol Alcohol produces the profoundest lesions in the brain and other organs, diseases that are called progressive These things, I say, you can depict to the patient, and sometimes you can rescue him from the habit, but not as a rule, for he has become addicted to it for life, and is not capable of breaking it off, because the force of his will is broken, too Most of the inebriate asylums of the country are failures The individual can be sent to an asylum, and so long as there, kept under observation, he will do very well, but the moment he is out from observation, he relapses, because, as I have said, the regular drinker has lost his will We do not expect to accomplish much by that method, or by our or other sermons, but we expect to accomplish more by good laws—by license laws, perhaps—by some means that will put the abundance of liquor beyond the reach of the majority of men It was found in Russia that the amount of crime was in exact ratio to the tax that was put upon liquor In the countries where people drink the milder wines, we do not find any of these diseases So, if we can do no more, we may impress upon the patient the wisdom of taking only the lighter drinks

PREMATURE DETACHMENT OF THE PLACENTA DURING LABOR AS A PROBABLE CAUSE OF STILL BIRTH WHEN NO OTHER CAUSES CAN BE ASSIGNED

BY H LANDIS GETZ, M D MARSHALTOWN, IA

For some years past we have entertained the view that the premature detachment of the placenta in otherwise normal labors, was occasionally the cause direct of "still birth," or the cause of the enfeebled condition of the child at birth, where only the most prompt and efficient measures which can be brought into practice by the accoucheur, are the means of establishing respiration, a perfect circulation, and consequently the life of the child, which but for prompt measures must otherwise have perished We believe that a child born where the placenta remains attached to the womb until the child is expelled from the mother never requires any assistance to promote or establish respiration, and that where such assistance is necessary there has been either a partial or complete *premature detachment* of the placenta, for a shorter or longer time prior to the expulsion of the child from the mother, and the circulation in the cord will be enfeebled or have entirely ceased in proportion to the length of time the partial or complete placenta detachment may have existed Our attention has been recently called to this subject in quite a decided manner, through the occurrence of two cases, which were of a very striking nature

CASE 1 A primipara, second stage of labor, lasted about two hours, labor normal in every particular, child well developed, heart action very feeble, no pulsation in cord perceptible, no effort at respiration, had hand upon abdomen over womb when child was expelled from mother, held hand in same position until removed to cut the cord, which was done within two minutes after the delivery of the child, and there was not the slightest contraction of the womb from the time of the pain which expelled the child to the time of cutting the cord, and when the cord was cut there seemed to be no necessity for a ligature, inasmuch as there was not the slightest hæmorrhage, prompt measures restored the child, which has since done well, and is now several weeks old and has not shown an unfavorable symptom The placenta was expelled by the first contraction of the womb after the expulsion of the child, about five minutes elapsing between the expulsion of child and placenta

CASE 2 A multipara, eighth pregnancy, labors previous all normal, present labor normal, except that the vertex caught upon the symphysis in such a manner as required the application of instruments to dislodge it, which was easily accomplished, conditions of child, etc , almost identical with case 1, above described, except that at least fifteen minutes elapsed before there was any voluntary effort at respiration, and at least half an hour before the respiration assumed any degree of certainty or regularity This child also was well developed, and when last seen was to all appearances well in every particular These cases to us, together with former observations of a similar nature, would, it seems to us, go far toward the establishment of the belief and fact of the possibility of the occurrence of the accident, and its effects as herein suggested If our theory is correct, then arises the question What are the causes of this premature placental detachment, or how can it happen? Several ideas suggest themselves to us

1 Where there is very large quantity of liquor amnii, and where the head for a time completely obliterates the outlet, where the space between the child and the wall of the womb is greater than the thickness of the placenta, this space filled with liquor amnii, and now as the forcible contractions of the womb come on the placenta having the liquor amnii as a bearing instead of the firm body of the child, is driven into the fluid, and torn from its attachments

2 Where the head is locked in the pelvis, and does not recede as each uterine contraction ceases, the relaxation of the uterine tissues may be so great as to leave a material space between the walls of the womb and the body of the child, so that when the womb again forcibly and suddenly contracts, and the bearing for the placenta is not immediately reached, the latter is in the meantime partially or completely severed from its attachments

3 Where a condition (owing to certain position or relation of body of child to placenta) exists, for instance, if the lower extremities doubled upon the body of the child should happen to be a few inches apart, the placenta happens to be attached immediately opposite this gap, the womb contracts, the bearing to the placenta is not exactly equable, and, as a consequence, there is a partial detachment of placenta

Westphal has shown that six per cent of these cases attempt suicide, but homicide is almost unknown When it does occur, it is accidental, in the effort to escape This man, we are told, wandered around the ward until he set himself on fire at the grate, and so profound was the anæsthesia that he paid no attention to the accident at all

Suppose, now, that you should see an individual lying in the street in an acute state of intoxication, or coma, and it should become a question to what the coma was due, how would you decide? PREMATURE DETACHMENT OF THE PLACENTA DURING LABOR AS A PROBABLE CAUSE OF STILL BIRTH WHEN NO OTHER CAUSES CAN BE ASSIGNED

BY H LANDIS GETZ, M D MARSHALLTOWN, IA

For some years past we have entertained the view that the premature detachment of the placenta in otherwise normal labors, was occasionally the cause direct of "still birth," or the cause of the enfeebled condition of the child at birth, where only the most prompt and efficient measures which can be brought into practice by the accoucheur, are the means of establishing respiration, a perfect circulation, and consequently the life of the child, which but for prompt measures must otherwise have perished We believe that a child born where the placenta remains attached to the womb until the child is expelled from the mother never requires any assistance to promote or establish respiration, and that where such assistance is necessary there has been either a partial or complete *premature detachment* of the placenta, for a shorter or longer time prior to the expulsion of the child from the mother, and the circulation in the cord will be enfeebled or have entirely ceased in proportion to the length of time the partial or complete placenta detachment may have existed Our attention has been recently called to this subject in quite a decided manner, through the occurrence of two cases, which were of a very striking nature

CASE 1 A primipara, second stage of labor, lasted about two hours, labor normal in every particular, child well developed, heart action very feeble, no pulsation in cord perceptible, no effort at respiration, had hand upon abdomen over womb when child was expelled from mother, held hand in same position until removed to cut the cord, which was done within two minutes after the delivery of the child, and there was not the slightest contraction of the womb from the time of the pain which expelled the child to the time of cutting the cord, and when the cord was cut there seemed to be no necessity for a ligature, inasmuch as there was not the slightest hæmorrhage, prompt measures restored the child, which has since done well, and is now several weeks old and has not shown an unfavorable symptom The placenta was expelled by the first contraction of the womb after the expulsion of the child, about five minutes elapsing between the expulsion of child and placenta

CASE 2 A multipara, eighth pregnancy, labors previous all normal, present labor normal, except that the vertex caught upon the symphysis in such a manner as required the application of instruments to dislodge it, which was easily accomplished, conditions of child, etc , almost identical with case 1, above described, except that at least fifteen minutes elapsed before there was any voluntary effort at respiration, and at least half an hour before the respiration assumed any degree of certainty or regularity This child also was well developed, and when last seen was to all appearances well in every particular These cases to us, together with former observations of a similar nature, would, it seems to us, go far toward the establishment of the belief and fact of the possibility of the occurrence of the accident, and its effects as herein suggested If our theory is correct, then arises the question What are the causes of this premature placental detachment, or how can it happen? Several ideas suggest themselves to us

1 Where there is very large quantity of liquor amnii, and where the head for a time completely obliterates the outlet, where the space between the child and the wall of the womb is greater than the thickness of the placenta, this space filled with liquor amnii, and now as the forcible contractions of the womb come on the placenta having the liquor amnii as a bearing instead of the firm body of the child, is driven into the fluid, and torn from its attachments

2 Where the head is locked in the pelvis, and does not recede as each uterine contraction ceases, the relaxation of the uterine tissues may be so great as to leave a material space between the walls of the womb and the body of the child, so that when the womb again forcibly and suddenly contracts, and the bearing for the placenta is not immediately reached, the latter is in the meantime partially or completely severed from its attachments

3 Where a condition (owing to certain position or relation of body of child to placenta) exists, for instance, if the lower extremities doubled upon the body of the child should happen to be a few inches apart, the placenta happens to be attached immediately opposite this gap, the womb contracts, the bearing to the placenta is not exactly equable, and, as a consequence, there is a partial detachment of placenta

at the point where there is practically no resistance or bearing

What can be done to avoid these accidents, if it is possible for them to occur—and our theories in the main are correct—we confess we have little to suggest, the principal remedy perhaps being in prompt delivery in all cases where the womb is fully dilated and there is nothing to contraindicate it by the pelvic and external soft parts When instruments are used, the pærineum should always be given ample time for yielding, so that it may not be unnecessarily lacerated

Nov 24, 1884

MEDICAL PROGRESS

OBSTETRICS AND GYNÆCOLOGY.

THE USE OF COLD IN LABOR —Dr Grognot (*Bull Gen de Therap*) recommends the use of cold to produce and increase labor pains It is well known that to palpate the abdomen in a pregnant woman, the hands must be of approximately the same temperature with that of the skin of the patient, otherwise if too cold the disagreeable sensation will produce immediate contraction of the muscular walls of the abdomen and prevent a proper examination But, if persisted in, this may extend to the uterus itself, and give the sensation of the presence of a regular globular tumor, contracting, not from the pressure, but from the effects of the cold There are uteri which contract upon the slightest touch, but they are rare, and pressure generally produces no such effect In consequence of these observations, Dr Grognot uses a wash basin or bucket of fresh water, into which, when it is deemed desirable to provoke pains or to accelerate labor, he places his hands for one or two minutes, and then applies them over the abdomen, and as fully as possible over the region which covers the antero superior surface of the uterus In a few seconds the patient complains of a pain and the hands are removed It is sufficient to use fresh water, as a greater degree of cold would not hasten contractions to any greater extent To this may be added manual pressure and manipulation It is generally not necessary to use this method more than ten or fifteen times The following are his conclusions

1 The application of cold provokes marked contractions during labor
2 They are normal in their effects
3 This method is without danger to the mother or child
4 It can be used independently and without instruments
5 It can be employed during all the stages of labor, for the expulsion of the foetus and also for the removal of the placenta

CHRONIC DYSENTERY TREATED BY VOLUMINOUS ENEMATA OF NITRATE OF SILVER —Dr Stephen Mackenzie has read a paper on this subject before the Clinical Society of London (*Med Times*) The mode of procedure he adopted was as follows The quantity of nitrate of silver to be used was dissolved in three pints of tepid water in a Leiter's irrigating funnel, which was connected by India-rubber tubing with an œsophageal tube with lateral openings The patient was brought to the edge of the bed and made to lie on his left side, with his hips well raised by a hard pillow The terminal tube, well oiled, was passed about eight or ten inches into the rectum, and the fluid allowed to force its way into the bowel by gravitation The injection rarely caused much pain, and often none It usually promptly returned, but when long retained it was advisable to inject chloride of sodium, to prevent absorption of the silver salt Various strengths had been used from thirty to ninety grains to three pints of water, but usually one drachm of nitrate of silver was employed The treatment was based on the view that, whatever the nature of dysentery, whether constitutional or local, in the first instance, the later effects were due to inflammation or ulceration of the colon, which was most effectually treated, as similar conditions elsewhere, by topical measures Sometimes one, sometimes two injections were required, and in some cases numerous injections were necessary, but in all the cases thus treated, many of which had been unsuccessfully treated in other ways previously, the disease had been cured The cases narrated were 1 In which the disease had lasted several years on and off, two injections were used and the case was cured in six weeks 2 Second attack, duration uncertain, four injections used, cured in five weeks 3 Duration two months, two injections used, cured in three and a half weeks 4 Duration five years, one injection used, cured in three weeks 5 Duration eighteen months, two injections used, cured of dysenteric symptoms, but remaining under treatment for diabetes 6 Duration fourteen months, one injection used, cured in seven weeks

Dr Carrington said that this treatment had been tried in the hospital at Greenwich without any remarkable effect, but the injections had not been so voluminous as those used by Dr Mackenzie, which might, perhaps, explain the fact The colon was usually capable of holding six pints of fluid, and the three pints used in some of the cases might possibly have failed to reach the affected parts

CHRYSOPHANIC ACID IN CUTANEOUS AFFECTIONS OF THE EAR —Dr Strequart (*Jour de Med*) reports five cases benefited by this treatment The first case was in a patient 31 years of age affected for six months with an eczema of the scalp, and for fifteen days with acute eczema of the right ear—thickening of the skin, liquid exudation, purulent and sanguinolent otorrhœa Ordered chrysophanic acid internally, in the dose of 2 centigrammes per day, and injections of a warm solution of boracic acid In two days the discharge diminished, the eruption became paler and the skin thinner Two days later there was desiccation and desquamation of the skin The dose of the drug was increased progressively to 5 centigrammes a day, when the stomach no longer tolerated it After eight days of treatment the affection had almost entirely disappeared Six months later there had been no recurrence The second case was in a patient 15 months of age, suffering from impetiginous eczema of the scalp of six weeks standing, which for fifteen days had involved the ears Two centigrammes a day were given, and in seven days the cure was complete The third case was three years of age, affected for three weeks with impetiginous eczema of the chin and right ear, same dose, on the fourth day desiccation and peeling of the skin, on the seventh day, cured Fourth case, a patient of four years, acute eczema of meatus and auricle of right ear, same treatment, cure on the seventh day Fifth case, patient 35 years of age, suffering for four months from a chronic eczema of the auricles of each ear, following double purulent otitis Was given 3 centigrammes of chrysophanic acid a day Less redness about the mastoid and parotid region, and diminution of sense of burning of auricles and meati in two days Notable amelioration in five days Complete cure in twelve days

Treatment of Amenorrhœa by Permanganate of Potash —Drs Ringer and Munell have used the permanganate of potash in 69 cases of amenorrhœa in solution or in pills, beginning with a dose of 6 centigrammes three times a day and increasing it progressively to 12 centigrammes This treatment has given excellent results in young girls, 18 to 25 who were affected with amenorrhœa from taking cold The treatment should be commenced several days before the time for the appearance of the menses The results of this treatment have been no less satisfactory in women from 35 to 40 years, in whom the amenorrhœa was symptomatic of repeated confinements and prolonged lactation On the other hand, if the amenorrhœa is in consequence of normal pregnancy, the treatment is perfectly inoffensive It remains inert if the amenorrhœa occurs in the last stages of phthisis In the first stages of phthisis, the permanganate may cause the menses to reappear, but it has no influence on the progress of the disease Finally, in young girls where the establishment of the menstrual period is retarded, it has but little effect

The use of the permanganate in solution is sometimes followed by nausea, vomiting and acute pain under the sternum This drug does not seem to act by modifying the composition of the blood, for it acts equally well with the plethoric and the chloro-anæmic

Ipecac in Minute Doses for Metrorrhagia —Dr Jules Cheron (*Rev Med Chis des Maladies des Femmes*) has used this drug in a large number of cases of metrorrhagia, without regard to the causes as to whether they were functional or symptomatic, and with marked success Its use for this purpose as an emetic is nothing new—as producing a slowing of the circulation and cardiac pulsations, but in minute doses, where it does not produce vomiting, or even nausea, it modifies, according to Dr Cheron, the excito-motor force of the spinal cord as with, but better than, bromide of potassium He uses of powder ipecac, freshly prepared, 0 20 centigrammes, divided into twenty papers, and gives one every hour, except the hour which follows a meal After having used the whole of the 0 20 centigrammes, the medicine is suspended for twelve hours, to be recommenced if the metrorrhagia has not been completely arrested

Vesical Injections of Nitrite of Amyle —Dr Dittel, of Vienna, recommends (*Sym Med Annales Maladies des Organes Genito Urinaires*) the use of injections of nitrite of amyle into the bladder when the urine is ammoniacal He prepares three drops of nitrite of amyle in solution in 150 grammes of water, and for each injection he uses a spoonful of the solution in a litre of water, with which he washes out the bladder by the use of the double sound The influence on the urine is very rapid, and after the first washing out the ammoniacal and insupportable odor is replaced by a very agreeable odor of ether

Subcutaneous Injections of Caffeine for Adynamia —M Huchard uses, at the Hospital Bichat (*Jour de Med*), subcutaneous injections of caffeine as an agreeable and satisfactory substitute for subcutaneous injections of ether, in adynamic affections that succeed hæmorrhages He considers the drug as preferable to ether from being less painful, and from having a favorable action upon the urinary secretion, and particularly upon cardiac contractility This makes the injections indicated in all typhoid and adynamic conditions (pneumonia, dothinenteritis, post-hæmorrhagic anæmia, etc) He uses the following formula

Sodium salicylate, 3 grammes 10 centigrammes
Caffeine, 4 grammes
Distilled water, 6 grammes, or q s for 10 cubic-centimeters Dissolve in a water-bath Each cubic-centimeter contains 0 40 centigrammes of caffeine

Sodium benzoas, 2 grammes, 95 centigrammes
Caffeine, 2 grammes, 50 centigrammes
Distilled water, 6 grammes, or q s for 10 cubic centimeters
Each cubic centimeter contains 0 25 centigrammes of caffeine

The tonic and stimulant action of caffeine is also utilized in the form of wine caffeine containing 0 10 centigrammes of the active substance to the spoonful, and preparations are also made from a West African drug called *Kola*, which contains more caffeine than does coffee

But caffeine is not only a tonic and stimulant, it is also a cardiac stimulant which sometimes gives admirable results in the last periods of asystoly, when the heart no longer responds or responds but imperfectly, to digitalis The drug will not act in affections of the heart and kidneys unless it is given in the large doses of 0 50 centigrammes to 2 grammes a day To assure its solubility it is necessary to mix it with salicylate of sodium, or better, with benzoate of sodium, as in the following formula

Distilled water, 300 grammes
Benzoate of sodium, } each 5 grammes
Caffeine, }
Two to six soup-spoonfuls daily

The Action of Salicylate of Soda upon the Uterus —M Balette has shown (*Jour de Médecine*) the good effects which follow the use of this drug in dysmenorrhœa, where the salicylate of soda quiets the pains and facilitates the discharge of the menstrual fluid A dose of from four to six grammes, taken in three divisions, gives excellent results, and often quiets the pains at the end of fifteen minutes or a half an hour But the drug has also another property which is less known, a menorrhagic action M Bucquoy has observed this influence, and M Balette cites several observations which show that the salicylate may provoke metrorrhagia in certain cases, or rather prolong the menses and increase the quantity of the blood-flow

This action may be explained as in the cases where the salicylates readily produce other hæmorrhages, as hæmaturia, and particularly epistaxis, as also vesical, pharyngeal, gastric and intestinal hæmorrhage

The production of abortion has also been attributed to salicylate of sodium, but the evidences are contradictory With several patients it would seem as if the abortive action was well manifested, with others, on the contrary, it had no effect In M Balette's experiments upon animals, the drug had no oxytocic action, and it would seem not to be abortive when given in moderate therapeutic doses But as there are women who are predisposed to abortion, it is advisable, during gestation not to give the salicylate of sodium without proper cause, and to watch carefully the degree of toleration in the individual to the drug

MEDICINE.

ON AGRAPHIA —Dr A Pitres (*Revue de Médicine*) considers this subject at some length He gives Charcot's definition, that agraphia is aphasia of the hand, as the most complete and concise that it is possible to apply to it The word agraphia was first introduced to science by M W Ogle in 1867, but Marce in 1856, was the discoverer of agraphia The trouble with his work is that it is not founded on the study of simple and precise clinical observations At present we recognize for the purpose of writing the combined use of several factors, viz

1 Visual memory, which gives us the remembrance of the form of letters, and their relative value in their innumerable associations in syllables and in words

2 Auditory memory, which gives us the remembrance of sounds and their value in phonetic language

3 Motor memory, which gives us the remembrance of efforts and muscular coordinations necessary to trace written characters correctly

Dr Pitres illustrates these assertions by detailing some well-defined cases, and arrives at the following conclusions

1 There exist close analogies between the physiological mechanisms which preside over the formation of speech and of written language There exist equally marked resemblances between the pathological disturbances which alter their functions

2 It is proper, then, to distinguish three forms of agraphia, corresponding to the three classic forms of aphasia as known at present These are

A *Agraphia by verbal cecity*, in which the patient cannot copy after an example, while he can still write his own thoughts, or from dictation

B *Agraphia by verbal surdity*, in which the patient cannot write from dictation, while he can still copy from an example or write out his own thoughts

C *Motor agraphia or graphoplegia*, in which the patient cannot write at all

3 Each of these forms of agraphia has been observed as isolated and distinct in patients whose intelligence was normal and whose motility was intact Several very precise observations of verbal cecity and of verbal surdity have been put on record Observations of motor agraphia are rarer, but two at least of such cases are recorded at present as demonstrating this condition satisfactorily

4 In the most of these pathological cases agraphia is associated with hemiplegia or with aphasia In such complex conditions, the diverse symptoms to be found in the same patient, must be considered as coexistent and not subordinated one to the other The complexity of the semiology in each particular case depends solely upon the variable topography and the greater or less extension of the cerebral lesions

UREA AS A POISON —MM N Grehant and Ch E Quinquand (*Jour de l'Anat et de la Physiol*) have published the results of a large number of experiments upon various animals by which they reach these conclusions

1 Pure urea is a poison which, in sufficient doses, produces convulsions and death, supervening after a variable length of time, dependent upon the dose employed

2 The mortal toxic dose in the blood of the rabbit is $^1/_{151}$, in the dog $^1/_{153}$, $^1/_{203}$, $^1/_{194}$

3 The fixation of urea in the tissues and blood does not seem to produce a diminution of muscular force

4 The effects produced by the urea are not due to the presence of ammonia in the circulation

5 When urea is injected into the blood, or when solutions of urea are used subcutaneously, the tissues take up great quantities of the urea

6 The toxic doses in man are in every respect comparable to those in animals Physiology and clinical facts reach the same conclusions, urea is a poison whose toxic dose can be determined with exactness

MATERIA MEDICA AND THERAPEUTICS.

ERGOT IN THE TREATMENT OF CONSTIPATION —Dr Granzio (*Allgemeine Medicinische Central-Zeitung, Practitioner*) reports two cases of constipation following the abuse of purgatives, relieved by ergot Three doses of 10 grains each were given at intervals of two hours, and were followed by a copious evacuation A second stool occurred spontaneously the next day, and after the administration of ergot in smaller doses for a few days a definite cure was obtained The constipation was due to atony of the muscular wall of the intestines

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 65 RANDOLPH STREET,
CHICAGO ILLINOIS

SATURDAY, JANUARY 17, 1885

STETHOSCOPES —In the first number of the current volume of the JOURNAL, at page 15, will be found an abstract of the views recently published by Haupt, in the *Aerztliches Intelligenzblate*, concerning the "Perception of Sound in Auscultation" The conclusion at which he arrives is, that the sounds are transmitted through the solid part of the stethoscope, and that the hollow part or tube is entirely superfluous Knowing that the question presented by Haupt had been thoroughly investigated, and the comparative value of solid and hollow or tubular stethoscopes fully tested clinically in this country many years since, we let the abstract appear solely for the purpose of re-calling attention to the subject, which is one of much clinical importance Even sooner than we expected the statements of Haupt have elicited the three following letters in reply, which so fully negative the views of Haupt, that we will give them instead of further comments of our own, only adding that we think we recognize in the letter signed "B" the words of one of the most experienced and eminent members of the profession in the New England States We also fully agree with his expression in the P S to his letter, to the effect that Camman's binaural stethoscope just as he left it, is really the best instrument for auscultatory purposes that we have

DENVER, COLORADO, Jan 8, 1885

TO THE EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

Dear Sir —I have just been reading your resumé, in the Jan 3d number, of an article by Haupt in the "*Aerztliches Intelligenzblate*," entitled "Perception of Sound in Auscultation" Allow me to ask Did Haupt present any solid "hearing staff" or an instrument built on the *solid* plan to substantiate his conclusion that "the bore of the stethoscope is quite superfluous"?

It is important to know if Haupt's conclusions are theoretical merely, in which case they are of doubtful value, or, if obtained by a comparison of instruments, with what imperfect stethoscope his solid instrument was compared

If I mistake not, there is something wrong in the gentleman's premises Most likely it is in the statement that the aid of the stethoscope "as a hollow resonator is lost, *as we use the instrument*, for the tube no longer acts as a resonator when we block up both ends of it" The fault lies in not appreciating that in a perfect instrument as to the transmission of sound, with large-sized tubes of gradually decreasing caliber from the bell to the ears, and with smooth, even, inner surfaces, the column of the contained air has imparted to it an impression of the transmitted sounds, which impression is carried on to the tympanum and thus serves to correct the sound given by the solid parts of the instrument With a suitable stethoscope this matter can be easily tested By putting cotton in one's ears, or by stopping up either or both ends of the binaural stethoscope, and thus making it more like a solid instrument, the dulling of the perception of the transmitted sounds can be appreciated I speak of a *suitable* instrument, because most of the cheap instruments now in the market are not so Such an one should combine the good qualities mentioned above, with such shaped bells as have broad impinging surfaces where they are pressed against the chest walls, and the coiled wire of the flexible portion imbedded in soft rubber, giving a smooth inner surface Messrs Chas Truax & Co, of Chicago, had the one made for me which I now have. It has all the improvements here recommended, and is a very satisfactory instrument I doubt if it can be equalled in the clear transmission of intra thoracic sounds by any solid "hearing staff" Hence these interrogatories Very respectfully,

CHARLES DENISON

EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

My Dear Doctor —In the issue of the 3rd instant you give a quotation from the *Medical Chronicle*, which gives to Haupt (*Aerztliches Intelligenzblate*) the credit of having shown that the vibrations started by the heart or lungs are not communicated to the ear through the column of air in the tubular stethoscope, but through the solid material of which the instrument is constructed

It will be a matter of interest to your readers to know that an ingenious physician of this city showed the same thing to the Chicago Medical Society about four years ago, but that he soon found that he was mistaken

I was not at the meeting when the discussion took place, but the next day the doctor called at my office and demonstrated to me the interesting fact that a watch placed against the chest piece of a stethoscope the good effects which follow the use of this drug in dysmenorrhœa, where the salicylate of soda quiets the pains and facilitates the discharge of the menstrual fluid A dose of from four to six grammes, taken in three divisions, gives excellent results, and often quiets the pains at the end of fifteen minutes or a half an hour But the drug has also another property which is less known, a menorrhagic action M Bucquoy has observed this influence, and M Balette cites several observations which show that the salicylate may provoke metrorrhagia in certain cases, or rather prolong the menses and increase the quantity of the blood-flow

This action may be explained as in the cases where the salicylates readily produce other hæmorrhages, as hæmaturia, and particularly epistaxis, as also vesical, pharyngeal, gastric and intestinal hæmorrhage

The production of abortion has also been attributed to salicylate of sodium, but the evidences are contradictory With several patients it would seem as if the abortive action was well manifested, with others, on the contrary, it had no effect In M Balette's experiments upon animals, the drug had no oxytocic action, and it would seem not to be abortive when given in moderate therapeutic doses But as there are women who are predisposed to abortion, it is advisable, during gestation not to give the salicylate of sodium without proper cause, and to watch carefully the degree of toleration in the individual to the drug

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, JANUARY 17, 1885.

STETHOSCOPES.—In the first number of the current volume of the JOURNAL, at page 15, will be found an abstract of the views recently published by Haupt, in the *Aerztliches Intelligenzblatt*, concerning the "Perception of Sound in Auscultation." The conclusion at which he arrives is, that the sounds are transmitted through the solid part of the stethoscope, and that the hollow part or tube is entirely superfluous. Knowing that the question presented by Haupt had been thoroughly investigated, and the comparative value of solid and hollow or tubular stethoscopes fully tested clinically in this country many years since, we let the abstract appear solely for the purpose of re-calling attention to the subject, which is one of much clinical importance. Even sooner than we expected the statements of Haupt have elicited the three following letters in reply, which so fully negative the views of Haupt, that we will give them instead of further comments of our own; only adding that we think we recognize in the letter signed "B" the words of one of the most experienced and eminent members of the profession in the New England States. We also fully agree with his expression in the P. S. to his letter, to the effect that Camman's binaural stethoscope just as he left it, is really the best instrument for auscultatory purposes that we have.

DENVER, COLORADO, Jan. 8, 1885.

TO THE EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Dear Sir.—I have just been reading your resumé, in the Jan. 3d number, of an article by Haupt in the "*Aerztliches Intelligenzblatt*," entitled "Perception of Sound in Auscultation." Allow me to ask: Did Haupt present any solid "hearing staff" or an instrument built on the *solid* plan to substantiate his conclusion that "the bore of the stethoscope is quite superfluous"?

It is important to know if Haupt's conclusions are theoretical merely, in which case they are of doubtful value, or, if obtained by a comparison of instruments, with what imperfect stethoscope his solid instrument was compared.

If I mistake not, there is something wrong in the gentleman's premises. Most likely it is in the statement that the aid of the stethoscope "as a hollow resonator is lost, *as we use the instrument*, for the tube no longer acts as a resonator when we block up both ends of it." The fault lies in not appreciating that in a perfect instrument as to the transmission of sound, with large-sized tubes of gradually decreasing caliber from the bell to the ears, and with smooth, even, inner surfaces, the column of the contained air has imparted to it an impression of the transmitted sounds, which impression is carried on to the tympanum and thus serves to correct the sound given by the solid parts of the instrument. With a suitable stethoscope this matter can be easily tested. By putting cotton in one's ears, or by stopping up either or both ends of the binaural stethoscope, and thus making it more like a solid instrument, the dulling of the perception of the transmitted sounds can be appreciated. I speak of a *suitable* instrument, because most of the cheap instruments now in the market are not so. Such an one should combine the good qualities mentioned above, with such shaped bells as have broad impinging surfaces where they are pressed against the chest walls, and the coiled wire of the flexible portion imbedded in soft rubber, giving a smooth inner surface. Messrs. Chas. Truax & Co., of Chicago, had the one made for me which I now have. It has all the improvements here recommended, and is a very satisfactory instrument. I doubt if it can be equalled in the clear transmission of intra-thoracic sounds by any solid "hearing staff." Hence these interrogatories. Very respectfully,

CHARLES DENISON.

EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

My Dear Doctor.—In the issue of the 3rd instant you give a quotation from the *Medical Chronicle*, which gives to Haupt (*Aerztliches Intelligenzblatt*) the credit of having shown that the vibrations started by the heart or lungs are not communicated to the ear through the column of air in the tubular stethoscope, but through the solid material of which the instrument is constructed.

It will be a matter of interest to your readers to know that an ingenious physician of this city showed the same thing to the Chicago Medical Society about four years ago, but that he soon found that he was mistaken.

I was not at the meeting when the discussion took place, but the next day the doctor called at my office and demonstrated to me the interesting fact that a watch placed against the chest piece of a stethoscope could be heard quite as well with the tubes of the instrument completely closed as when they were free. He therefore concluded that the vibrations were transmitted through the material of which the instrument was made, and he reasoned that if the stethoscope were made of a solid piece of wood the respiratory sound would be transmitted to the ear with more intensity than through the tubular instrument.

I suggested that we try the experiment over the trachea, from which the most intense respiratory sounds are to be obtained. We did so, and found that the tracheal sounds could not be heard at all when the tubes were plugged. I have often used the solid stethoscope in auscultatory percussion, but I have never been able to hear the respiratory sounds through it.

Theoretically, the solid stethoscope is all that Haupt claims for it, but practically it is worthless, and consequently we conclude that something is wrong with the theory. Any one who will take the trouble to plug the tubes of his stethoscope, and then attempt auscultation of the lungs, may speedily convince himself that Haupt is not correct in his conclusions.

E. FLETCHER INGALS.

64 State street, Jan. 10, 1885.

BOSTON, Jan. 8, 1885.

DR. DAVIS:

Dear Sir:—In the last numbers of the JOURNAL there is an extract (page 15), on "Perception of Sound in Auscultation," by Haupt. The writer theorizes a great deal, and his final conclusion is "that the bore of the stethoscope is quite superfluous, and a solid 'hearing staff' with a wide ear piece and a wide chest piece is the theoretically perfect instrument."

I *theorized* about thirty years since in the same manner, but *facts* upset my theory. My three *solid stethoscopes* remain now as relics of past experiments that were fruitless. Soon after these futile attempts on *theoretical grounds*, that skillful auscultator, Dr. C. P. Camman, of New York, kindly sent to me one of his Binaural Stethoscopes which compelled me to give up *all single* stethoscopes, whether perforated or not.* This admirable instrument *proves* that the position theoretically taken by Haupt (even the "vibrations started by the heart and lungs are incompetent to impart audible vibrations to a light medium like air,") is wholly unfounded in facts. Probably Haupt never saw a Camman stethoscope, or he would never have advanced such opinions.

Yours truly, B.

COLLECTIVE INVESTIGATION OF DISEASE.—At the last annual meeting of the Pennsylvania State Medical Society, a committee was appointed on this subject, consisting of Drs. James Tyson, Charles R. Mills, and Robert N. Chase. A letter from the chairman of the committee, Dr. James Tyson, states that they have prepared a circular and cards on which to record observations for acute pneumonia, chorea, and acute rheumatism, and endeavored to place them in the hands of every member of that Society. If any member has been accidentally omitted, he can obtain copies by applying to the chairman of the committee, 1506 Spruce street, Philadelphia, Pa.

The cards and questions and diseases are the same as used by the committee of the British Medical Association, for the purpose of making the returns capable of comparison in both countries. The parties receiving these cards are requested to fill and return them to the Chairman of the Committee before the first day of April, 1885.

At the annual meeting of the Illinois State Medical Society, held in May last, a committee was appointed on the same subject, consisting of Drs. N. S. Davis, J. H. Hollister, J. F. Todd, E. P. Cook, and G. Wheeler Jones. This committee had printed, memoranda and cards in relation to the same diseases mentioned above and some others, and through the Secretary of the Committee, Dr. J. F. Todd, of Chicago, they were distributed to a large part of the members of the Society more than three months since. How many have been filled and returned to the Secretary we have not learned. But it is very desirable that all should be returned to the Secretary of the Committee before the first of April next. We think a committee on the same subject was appointed by the Ohio State Medical Society, and perhaps by some others. As this method of investigation has now become international, we would feel greatly obliged for information directly from all existing committees of State Societies in this country, that we may be prepared to report the exact degree of progress thus far made, to the next meeting of the American Medical Association, and also to the Secretary General of the International Collective Investigation Committee in London.

ANNALS OF SURGERY.—We have just received the first number of this new periodical, published simultaneously in the United States and Great Britain, and edited by L. S. Pilcher, M. D., Brooklyn, N. Y., and C. B. Keetley, F. R. C. S., London, England. The number contains 96 pages on good paper, and published in good style by J. H. Chambers & Co., of St. Louis, Mo., at $5 per annum. Its pages are devoted exclusively to surgical science and practice, and the reputation of the editors is sufficient assurance that it will be worthy of the patronage of all interested in the practice of that department of medicine.

---

*Of late years, the manufacturers of the Camman double stethoscope divide it into two parts and fail to give to it the proper curves laid down by Camman. I deem this unfortunate for the profession, although it is still far superior to any *single* stethoscope.

OMISSIONS —In the list of permanent members of the American Medical Association, published in the JOURNAL of December 27, 1884, the names of Warren W Foster, M D, Putnam, Conn, and P C Williams, M D, Baltimore, Md, were accidentally omitted In the same list the residence of Dr G B Ward should be Fairbank, *Iowa*, instead of Ohio

SOCIETY PROCEEDINGS

SUFFOLK DISTRICT MEDICAL SOCIETY.

Albert N Blodgett, M D Secretary

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE

BOSTON, MASS, Dec 10, 1884

The meeting was called to order at 8 o'clock, by Dr R T Edes, P M, chairman

Dr H I Bowditch asked the privilege of addressing the Section for a few minutes, prior to the transaction of the business of the evening, and spoke as follows

Before we enter upon the regular business of this Section, I beg permission to announce the death of one of the ablest of the members of the Massachusetts Medical Society I allude to Henry A Martin He was, in my estimation, one of the strongest of the medical men it has been my fortune to meet either here or elsewhere His long residence in Roxbury, and his frequent intercourse with the physicians and surgeons of Suffolk and Norfolk counties, seem naturally to call upon us, who as a Section of the State Society meet first after his death, to take some notice of that event, and of the loss which the profession has sustained

Dr Martin died of diabetes, quietly, and apparently without suffering, during the forenoon of December 7, 1884 He had been fully aware for two years that the disease had fastened upon him, but he made little or no complaint, even to his family, and kept steadily at professional work until within a few past weeks Finding that his strength was gradually but surely lessening, he had thought of resigning all laborious out-of door practice and attending only to consultations at his office During the last weeks especially, his physical debility was greatly increased, and he kept his bed, but with no improvement

Believing that death was near at hand, he calmly bade farewell to his family, and soon after fell into a quiet sleep, from which he never awoke Let us hope that such a tranquil ending of this life may be vouchsafed to us all

In looking upon Dr Martin's life and character, we must, I think, admit that in most of his salient points he was a man *"sui generis"* I at least know of no one like him Intellectually he was far above most persons I have met, and physically he was one of the tallest and seemingly one of the most stalwart

In conversation, not only upon medical subjects, but upon a large range of topics, some of them widely removed from professional thought, he was superior to the majority of men He had studied deeply into the history of medicine In this department I know but one of our living associates who could approach him He gloried in the greater heroes among the medical men of the past Especially was he drawn to any one who by native vigor of intellect, and perhaps fierce professional contests, had won for himself fame in spite of all the babbling opposition of men who apparently hated him because of his very superiority to themselves For example, he sympathized heartily with that giant of our profession, grand old Ambrose Paré, who gained his ever enduring fame in spite of the sneers of the robed professors of the School of Medicine at Paris, and the carping criticisms of smaller men in the profession at large From a similar superiority of mind, and perhaps we may allow, from an apt readiness and joy in intellectual controversy, and from the fact that he never concealed an opinion though it struck rather severely, or perhaps sarcastically at even a friend's favorite notion, some have been led to think that Dr Martin was too pugnacious Truth compels me to admit that at times he may have been almost severely hypercritical in allusion to the writings or actions of others Especially was this trait manifested whenever or wherever he knew there was a lack of fair dealing on the part of an opponent But he was always a brave and frank-speaking antagonist I have had some sharp passes with him at times, but our friendship was never marred by them Nay more—I can say truly that my respect for him has always been rather increased than lessened by these contests, for I found him always open and fair in his opposition to my views Anything like cant or hypocrisy or unfair dealing, exhibited by an opponent, seemed to awaken in him a sort of fury, and he unsparingly used the lash upon his antagonist With a kind of Martin Luther violence he would at such times hurl defiance at anything or person that arose before him, and right manfully he would defend the position he had taken I grieve to say that, in consequence of this peculiarity, some of the more sensitive of those whom he felt himself called upon to criticise may not hold his memory in their hearts so gratefully or so inspiringly as I do I shall always regret his loss, because our relations were always friendly, notwithstanding an occasional difference in opinion, and from him I could often gain excellent information which I could get from none else

Before closing these remarks, which are so much of a merely personal character, I would refer to the fact that in addition to having been an able medical practitioner amongst us, he has been of inestimable advantage to every community in the world where animal vaccination is now used His energy and decision of character, his knowledge of the past, have brought us all back to first principles on vaccination, as proposed by Jenner

One at least of his surgical devices is almost universally used, not only in this country, but in Europe, and probably elsewhere where surgery is practiced

For the above reasons and because he was an able practitioner of medicine and surgery for many years amongst us, and because medicine has been helped onward by his life's work, I have wished that due honor should be paid to the memory of our dead associate

Believe me, gentlemen, you will wait for a long time before a man comparable with him will arise amongst you

By motion of Dr Blodgett, seconded by Dr J P Reynolds, Dr Bowditch was requested to convey to the family of Dr Martin the regrets of the Section at the loss of one of the distinguished members of the medical profession

SACCHARATED OXIDE OF IRON

Dr G L Walton exhibited a preparation of iron to which he had alluded some months ago in a published article, but which had not become generally known to the profession He said

It may possibly be remembered that I called attention [1] some time since to several agreeable iron preparations in common use in Germany, but not as yet introduced into America The merits of one of these preparations especially impressed me, namely, the so-called *Eisenzucker* (*Ferrum Oxydatum Saccharatum Solubile*), and I am glad to be able to show a specimen of it this evening, and to state that Metcalf & Company have undertaken its preparation, with this very satisfactory result It is a brownish red powder, of a very agreeable, sweet taste, completely soluble in five parts of water, and containing three per cent of metallic iron It does not discolor the teeth, and on account of its ready solubility may be taken for an indefinite length of time without affecting the digestion, even in cases where iron is otherwise ill borne It will be found especially valuable in chlorosis, for susceptible nervous patients and for children The dose is five to twenty grains three times a day, to be taken in water or in powder Most convenient and agreeable will be found the tablets, of which I have here five and ten grain specimens Mr Davidson assures me that this particular sample contains three and one-half per cent of iron by actual assay He also tells me, it may not be out of place to state, that he finds the precautions given me by the Leipzig pharmacist, Herr Blaser, of the utmost importance, and that a much more satisfactory result is reached by following his directions (detailed in the article already alluded to) than by following simply those of the pharmacopœia The difficulty of making the preparation may have had something to do with the postponement of its introduction in this country Its value, however, once recognized, I feel sure it will be generally adopted, and it is rather remarkable that among the needlessly multiplied and unsatisfactory forms of iron in American pharmacy this really elegant preparation has been so long overlooked To show that it is not identical with, and that it is far superior to, the saccharated carbonate of iron, I have brought a specimen of the latter, which has very much the color and general appearance of dirt, and is not particularly agreeable to the taste I pass around two bottles containing about five grains each of the powders and half an ounce of water It will be seen that, while the *Eisenzucker* makes a perfectly clear red solution, the carbonate is only partially dissolved, giving a murky mixture with a black residue (Dr Edes asked for the composition, saying that it could hardly be an oxide if soluble in water) In answer to Dr Edes I cannot find that the chemical formula has been made out It is certainly more than doubtful if it is really an oxide, notwithstanding its name It is mentioned in the United States Dispensatory under *Ferri Peroxidum Hydratum* as a *so called* oxide of iron adopted in the German pharmacopœia The process of manufacture was then described briefly

In answer to Dr Webber, Dr Walton said that he did not know how long the solution in water remained unchanged, but that it did so for several days he could state with certainty from observation

Dr J J Putnam then presented the first paper of the evening, entitled

A STUDY OF THE DEVELOPMENTAL DISEASES OF THE NERVOUS SYSTEM,

which is reserved for publication

Dr P C Knapp presented a very complete and exhaustive study of

CUTANEOUS AND DEEP REFLEXES,

extending over a long time and comprising several hundred observations, an abstract of which is here given —

The observations were made upon 239 patients in the nervous and renal service at the Boston City Hospital

The frequency of absence of the cutaneous reflexes was as follows

	Cases Examined	Present	Absent
Plantar	234	217	17
Cremaster	167	146	21
Gluteal	179	113	66
Abdominal	239	142	97
Epigastric	239	97	142
Erector spinæ	178	45	133
Scapular	177	15	162

In nearly every case in which the plantar and cremaster reflexes were absent there was either some lesion of the reflex arc, as in neuritis or myelitis, or some cerebral disturbance like coma, hemiplegia, or convulsions No pathological cause could be assigned for the absence of the other reflexes When the reflexes differed on the two sides it was usually significant of some unilateral disturbance of the nervous system, but in one or two cases no such disturbance could be made out

The frequency of absence of the deep reflexes was as follows —

---

[1] Boston Med and Surg Journal, January 12 1888

	Cases Examined	Present	Absent
Patellar	239	192	47
Tibial	231	18	213
Ankle clonus	238	12	226
Toe clonus	239	0	239
Triceps	239	198	41
Radial	239	131	108
Ulnar	239	61	178
Extensors of wrist	239	25	214
Wrist clonus	239	0	239
Costal	234	161	73
Lumbar fascia	178	33	145
Spine of scapula	178	45	133

The patellar reflex was also tested in eighteen patients under ether, and was found absent in six

The patellar reflex was found absent not only in cases of myelitis, locomotor ataxia, multiple neuritis, etc, where there was evidence of lesion of the reflex arc, but also in many cases of cerebral disturbance, like coma, cerebral hæmorrhage, and obscure cerebral disease, especially in alcoholic subjects The theory was advanced that such disturbances in the brain might have an inhibitory action upon the reflex centres in the cord, abolishing their action

The tibial reflex was found usually in cases where the patellar reflex was exaggerated, but was not necessarily pathological

Ankle clonus was found four times immediately after convulsions, in other cases there was disease of the lateral columns Its presence was regarded as always pathological

In a few cases of exaggerated patellar reflex, patellar clonus was tested, and was found in five cases, in four of which there was disease of the lateral columns It was regarded as pathological

The presence of the reflexes of the upper extremity was found to be very common The cause of absence was not clear

The costal cartilage reflex was found very often, and no clear relation between its presence and the existence of phthisis was apparent The other reflexes were unimportant

A difference of the deep reflexes on the two sides was usually significant of unilateral nervous disturbance, but as with the cutaneous reflexes, one or two cases were found where no such disturbance could be made out

Dr Webber said that it gave him pleasure to testify to the correctness of the observations, as they were made when Dr Knapp was house officer, during Dr Webber's term of service at the City Hospital He was able to "control" many of Dr Knapp's experiments, and was satisfied that they were thoroughly reliable They constitute a valuable addition to our recorded knowledge upon the character or various reflexes under a great variety of conditions

TENDON REFLEX AFTER FRACTURE OF THE PATELLA

Dr Walton also introduced a cast of a knee, which he felt sure would be of interest, not only from the rarity of the case, surgically considered, but also in connection with Dr Knapp's paper The cast was obtained (through the kindness of Dr W J Otis) from a patient who was under treatment in the nervous Out-Patient Department of the Massachusetts General Hospital for another trouble, but who had an ununited fracture of the patella, with separation of the fragments measuring six inches when the knee was flexed, three and a quarter inches when extended The only difficulty experienced in walking, by the way, was in going up and down stairs The interesting point in connection with the subject was that while no reflex could be obtained by striking below the knee, a distinct reflex followed the tap just above the upper fragment, the muscle being felt to contract, the patella fragment to be drawn up, and the skin over the joint to retract, although, of course, no motion of the foot followed

Dr Edes spoke of the varying results which will be obtained according as the blow is struck with a greater or less amount of force, and penetrates more or less deeply into the tissues The study of the phenomena of the patella is very interesting This is entirely absent only in those cases in which the nervous centers may be supposed to be diseased

Dr Putnam moved that the report upon the recent epidemic of cholera in Paris, which the secretary had been requested to prepare, be postponed to the next meeting Adjourned at ten o'clock

DOMESTIC CORRESPONDENCE.

DEAD TEETH IN THE JAWS.

To the Editor of The Journal of the American Medical Association —*Sir The Medical Record* of November 8th contains a reply from Dr Samuel Sexton to gentlemen who have criticised in the columns of that journal, his previous article on "Dead Teeth in the Jaws", and I beg space to present some views on this long neglected, but very important subject of lesions of the dental organs

If, by means of this discussion, members of the profession are brought to more fully realize the value of faithfully bestowing upon the teeth the care essential to their preservation—of adopting proper hygienic measures to this end, and of appreciating the difference between the scientific treatment of dental diseases and the treatment too often resorted to by uneducated dentists, the laity as well as the profession at large will be greatly benefited thereby

Dr Sexton says "The retention in the jaws of teeth which are diseased, from death of the pulp or from caries, have become irremediably sensitive to thermal influences, or have been deprived of adequate periosteal nourishment through calcareous formations about the roots, very frequently gives rise to nervous diseases about the head I am convinced that these reflected nerve influences manifest themselves much oftener since dentistry has come more extensively into practice during the present generation, and greater efforts are made to retain defective teeth in the jaws"

That diseases of the teeth are often the center from versally used, not only in this country, but in Europe, and probably elsewhere where surgery is practiced

For the above reasons and because he was an able practitioner of medicine and surgery for many years amongst us, and because medicine has been helped onward by his life's work, I have wished that due honor should be paid to the memory of our dead associate

Believe me, gentlemen, you will wait for a long time before a man comparable with him will arise amongst you

By motion of Dr Blodgett, seconded by Dr J P Reynolds, Dr Bowditch was requested to convey to the family of Dr Martin the regrets of the Section at the loss of one of the distinguished members of the medical profession

SACCHARATED OXIDE OF IRON

Dr G L Walton exhibited a preparation of iron to which he had alluded some months ago in a published article, but which had not become generally known to the profession He said

It may possibly be remembered that I called attention [1] some time since to several agreeable iron preparations in common use in Germany, but not as yet introduced into America The merits of one of these preparations especially impressed me, namely, the so-called *Eisenzucker* (*Ferrum Oxydatum Saccharatum Solubile*), and I am glad to be able to show a specimen of it this evening, and to state that Metcalf & Company have undertaken its preparation, with this very satisfactory result It is a brownish-red powder, of a very agreeable, sweet taste, completely soluble in five parts of water, and containing three per cent of metallic iron It does not discolor the teeth, and on account of its ready solubility may be taken for an indefinite length of time without affecting the digestion, even in cases where iron is otherwise ill borne It will be found especially valuable in chlorosis, for susceptible nervous patients and for children The dose is five to twenty grains three times a day, to be taken in water or in powder Most convenient and agreeable will be found the tablets, of which I have here five and ten grain specimens Mr Davidson assures me that this particular sample contains three and one-half per cent of iron by actual assay He also tells me, it may not be out of place to state, that he finds the precautions given me by the Leipzig pharmacist, Herr Blaser, of the utmost importance, and that a much more satisfactory result is reached by following his directions (detailed in the article already alluded to) than by following simply those of the pharmacopœia The difficulty of making the preparation may have had something to do with the postponement of its introduction in this country Its value, however, once recognized, I feel sure it will be generally adopted, and it is rather remarkable that among the needlessly multiplied and unsatisfactory forms of iron in American pharmacy this really elegant preparation has been so long overlooked To show that it is not identical with, and that it is far superior to, the saccharated carbonate of iron, I have brought a specimen of the latter, which has very much the color and general appearance of dirt, and is not particularly agreeable to the taste I pass around two bottles containing about five grains each of the powders and half an ounce of water It will be seen that, while the *Eisenzucker* makes a perfectly clear red solution, the carbonate is only partially dissolved, giving a murky mixture with a black residue (Dr Edes asked for the composition, saying that it could hardly be an oxide if soluble in water) In answer to Dr Edes I cannot find that the chemical formula has been made out It is certainly more than doubtful if it is really an oxide, notwithstanding its name It is mentioned in the United states Dispensatory under *Ferri Peroxidum Hydratum* as a *so called* oxide of iron adopted in the German pharmacopœia The process of manufacture was then described briefly

In answer to Dr Webber, Dr Walton said that he did not know how long the solution in water remained unchanged, but that it did so for several days he could state with certainty from observation

Dr J J Putnam then presented the first paper of the evening, entitled

Dr Putnam moved that the report upon the recent epidemic of cholera in Paris, which the secretary had been requested to prepare, be postponed to the next meeting Adjourned at ten o'clock

DOMESTIC CORRESPONDENCE.

DEAD TEETH IN THE JAWS.

To THE EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION —*Sir The Medical Record* of November 8th contains a reply from Dr Samuel Sexton to gentlemen who have criticised in the columns of that journal, his previous article on "Dead Teeth in the Jaws", and I beg space to present some views on this long neglected, but very important subject of lesions of the dental organs

If, by means of this discussion, members of the profession are brought to more fully realize the value of faithfully bestowing upon the teeth the care essential to their preservation—of adopting proper hygienic measures to this end, and of appreciating the difference between the scientific treatment of dental diseases and the treatment too often resorted to by uneducated dentists, the laity as well as the profession at large will be greatly benefited thereby

Dr Sexton says "The retention in the jaws of teeth which are diseased, from death of the pulp or from caries, have become irremediably sensitive to thermal influences, or have been deprived of adequate periosteal nourishment through calcareous formations about the roots, very frequently gives rise to nervous diseases about the head I am convinced that these reflected nerve influences manifest themselves much oftener since dentistry has come more extensively into practice during the present generation, and greater efforts are made to retain defective teeth in the jaws "

That diseases of the teeth are often the center from which pain is reflected to the eyes, ears and other parts, all experienced clinical observers must admit. But that these pathological conditions of the teeth, from which reflected pain has its origin, can be and are successfully treated and cured with rare exceptions, as effectually as any other diseases, is a fact too well established to be set aside.

It is not possible to describe in this letter the methods by which the various diseases of the teeth are treated, but suffice it to say that "teeth which are diseased from death of the pulp or from caries" *do not* "become irremediably sensitive to thermal influences." In proof of this statement, many thoroughly educated medical men, practicing the specialty of dental surgery, will testify.

"Teeth deprived of adequate periosteal nourishment, through calcareous formations about the roots, very frequently give rise to nervous diseases about the head." To this statement I assent, but dissent as to the remedy not mentioned but implied, *i. e.*, the removal of the teeth. If the calcareous deposits mentioned have destroyed so much of the pericementum together with the alveolar processes as to render the teeth very loose, if, indeed, the teeth have lost their bony support and are retained by means of a remnant of pericementum only, they can not, of course, be restored to permanent health and usefulness, and their removal is, therefore, indicated. Teeth in this condition "frequently give rise to nervous diseases about the head."

On the contrary, if the calcareous deposits have not destroyed the pericementum and alveolar processes to a very great extent, the condition is amenable to successful treatment and cure. In answer to the assertion that "Reflected nerve influences manifest themselves much oftener since dentistry has come more extensively into practice during the present generation," I would say, that with equal propriety it might be said that reflected nerve influences manifest themselves more frequently since gynæcology has come more extensively into practice. To attribute the obvious increase of nervous diseases during the present generation to diseases of the teeth is a statement not only "sweeping," but "overdrawn." *Much harm* is no doubt done by some of the modern appliances "for retention in the mouth of substitutes for absent teeth," and the unhealthy state of the gums and contiguous parts, established and maintained by the presence of these substitutes, unquestionably give rise in many cases to reflected pain.

When Dr. Sexton attempts to establish a *law* governing the management of diseased teeth, it must be based upon more substantial grounds than those which he presents. The case related of his patient, the "medical man, who practices dentistry," and who was convinced that an inflammation of one of his ears began from the time the upper second molar of that side was treated for a diseased pulp, is simply an assumption, on the part of the patient, that the ear trouble had its origin from the diseased tooth, and the patient's diagnosis of his own case seems to have been accepted by Dr. S. as conclusive. The ear disease in this case may have emanated from the diseased tooth, but no evidence is produced to that effect. In regard to the query as to "whether it is safe practice to retain dead teeth in the jaws," I would say that thousands of people in our own country have had pulpless (not dead) teeth in their jaws many years, which are exempt from pericemental disease, and which serve all the purposes for which teeth were provided. To ask whether it is safe practice to retain these, so-called, dead teeth in the jaws when they have been comfortable and useful from ten to forty years and promise to remain so through life, seems like a proposition too injudicious to need comment. While the death of the pulp results in "cutting off the source of nutrition from the dentine," it does not follow "that in a large number of instances irritation can not be easily controlled."

Neither does the tooth become a foreign substance. The dentine and the enamel are, of course, no longer nourished after the death of the pulp, but their resisting structure renders them capable of maintaining their integrity many years after the pulp has been removed, and the pericementum will nourish the cementum and thereby retain the tooth in its alveolus in a comfortable condition. In order, however, to thus retain the tooth and prevent inflammation from supervening, the devitalized pulp must be removed, the pulp canals thoroughly disinfected and filled with a plastic material which hardens when in position. Dr. S. most clearly exhibits his imperfect knowledge of the dental operations in vogue, when he says: "Inflammation of exposed dentine cannot surely be entirely arrested in any case by filling the pulp cavity with any known extraneous material, and especially is handicraft wanting to even imperfectly protect the minute and often tortuous canals leading down to the apical foramina of the majority of the teeth." To arrest "inflammation of exposed dentine by filling the pulp cavity," in the opinion of Dr. S. would seem to be most desirable. How a tissue without nourishment and consequently without vitality can take on or maintain inflammation is beyond comprehension. The impervious filling which I have herein mentioned will close the apical foramina, together with the canal, which "in the majority of cases" *is not* tortuous to a degree of rendering the perfect filling of the root difficult or uncertain, and the assertion that the dental surgeon "is able only to offer a hopeful but uncertain prognosis in these cases" is contrary to well established fact. There are no diseases to which mankind is heir more scientifically and effectually cured than the diseases of the teeth in question.

Again. "The dead tissues of the dentine will sooner or later, most likely, be transmitted through the tissues of the cementum to the periosteum." Communication between the lacunæ and canaliculi of the cementum with the tubuli of the dentine is not free; indeed, it seldom exists, hence it cannot be "that through the periosteum alone the dentine may long derive some nourishment."

About 22,000,000 of teeth are annually extracted in the United States, and I regret to say that this enormous loss of teeth is to no small extent due to the indifference manifested by physicians in the anatomy, physiology and pathology of these organs It is a fact that no one will attempt to gainsay, that hygienic measures directed toward the preservation of the deciduous set, if understood, are seldom recommended by the general practitioner to the families under his charge The premature loss of these teeth paves the way for early lesions of the permanent set The pain resulting from advanced caries of the deciduous teeth, owing to the difficulties encountered in controlling the patient, is not easily treated, moreover, the injurious impressions thus made upon the system of the child abide through life There is no doubt that hundreds of thousands of teeth are unnecessarily extracted each year, and then drugs are given with a view of curing the patient of the disorders of digestion and other abnormal conditions which follow, and which in turn arise from imperfect mastication of food, verily for the want of teeth

We need to know "what's the matter" in the treatment of these " nervous diseases about the head," as in all others, and apply a remedy which will bring the abnormal tissues back to health Too often, indeed, has it happened that patients, by advice of their medical attendants, have submitted to a loss of many, and in some instances all their teeth, in the vain endeavor to get relief from trigeminal neuralgia You may ask, Why this useless loss of teeth, and all the evils resulting therefrom? Because the advice given was not wise, the etiology of the affection was not understood

There are certain pathological conditions of the teeth which have not been mentioned in this discussion, and which give rise to reflected pain to the eyes, ears and other parts

Exostosis of the fangs of teeth and nodules of calcific matter within the pulp canals in contact with a living pulp The former of these conditions has been regarded incurable, the removal of the tooth with the united bony tumor being indicated In favorable cases, however, this tumor may be excised and removed without removing the tooth The pulp nodules or calcified deposits within the pulp chamber may be, in a large majority of cases, successfully removed without sacrificing the tooth

No one approves more than I the removal of the causes of disease It is no more necessary to extract a tooth at the root of which an alveolar abscess has formed than it would be to amputate a limb for the cure of an abscess of the medullary substance of its bone Disease of the eye sometimes requires that it be enucleated, but the honest, skilled ophthalmologist *would not* remove the eye when he *knew* he could restore it to usefulness The spirit of the teachings of Dr Sexton's articles is far from being progressive Nor is this all, many assertions are not based upon fact, but upon erroneous impressions Our duty to our profession and the laity is not to destroy, but to save, and while ignorance is ever working its mischief in all vocations in life, it is not just to accept the results of such work as a basis upon which to found a law

TRUMAN W BROPHY, M D, D D S,
Professor of Dental Pathology and Surgery in the Rush Medical College Chicago
125 State street, Chicago

NEW YORK LETTER.

NEW YORK, Dec 20, 1884

For some time past the subject of cholera has received a good deal of attention in the societies here, and it may, perhaps, be of interest to note the views of some of the prominent medical men of New York in regard to Koch's theory of the disease so far as they have been expressed at these meetings The one who has expressed most fully and forcibly his belief in the probable correctness of the opinions of Koch is Dr Austin Flint, Sr That Dr Flint would be likely to take this position whenever he enunciated his convictions on the subject was rendered almost certain by the elaborate paper which he read in support of the essential dependence of tuberculous disease on the *bacillus tuberculosis* at the first public meeting of the New York County Medical Association in January last At the October meeting of the same society he read an equally elaborate paper on "The Parasitic Doctrine of Epidemic Cholera," in which he maintained that in order to form an opinion as to whether the disease was due to a specific micro-organism, it was not necessary to have personally verified the evidence which the microscope afforded, but that this claim, like many in courts of law, was to be substantiated or rejected on the testimony of a sufficient number of competent judges, such as alone could arrive at any sound conclusions It was logically certain that the diseases now classed as infectious diseases involved each a distinct specific causative agent of some kind, and that this agent was a living organism was the most rational supposition It was, therefore, noteworthy that the discovery of micro-organisms as causes of infectious diseases, so far from being in opposition to previous views, was, in reality, a confirmation of the prevailing views of the ætiology of these affections At the present time there was no room for doubt as to the dependence of certain infectious diseases on specific micro-organisms, and if it were demonstrated (as had indeed been done in the case of several) that any single one of these diseases was caused by a specific parasitic organism, it certainly seemed to be a rational inference that they all have a similar causation In regard to Koch's researches in epidemic cholera, he said that if it were established that the comma bacillus was invariably present in the disease, and that this parasite was never present except when the cholera existed, as claimed, it would be logically certain that there was an essential pathological connection between this parasite and the disease, but the crucial test of inoculation would be required for determining a causative relation between the two In tuberculosis the proof that the parasite peculiar to that affection, after a series of cultivations, was capable of producing the disease by inoculation, was absolute, but up to that time Koch had reported failure in his efforts to obtain similar proof in the case of cholera A few days before Dr Flint read his paper, however, there was first published in this country an account of the experiments of Rietsch and Nicati at Marseilles, in which they claimed to have succeeded in producing cholera in the case of dogs, guinea-pigs and other animals by the introduction of a pure culture of comma bacilli into the duodenum, after ligation of the ductus choledochus Still, failure to inoculate would by no means disprove the parasitic doctrine of cholera, since it had been shown that all animals were not susceptible to the morbific action of micro-organisms which were known to be the causative agents of specific diseases in man Aside from this positive proof, there were certain ascertained facts which aim to sustain the parasitic doctrine of cholera If it were accepted that, reasoning by analogy, all infectious diseases are regarded as parasitic, the pathogenic claims of the comma bacillus over other intestinal bacteria seemed, with our present knowledge, to be paramount There are certain well-marked lesions of the mucous membrane of the small intestine which are either due to the presence of this parasite, or they furnished a peculiar soil for its cultivation, in the latter point of view the parasite being a product of the lesions Now, epidemic cholera, in all parts of the world except India, was an exotic disease and of rare occurrence, and it seemed, therefore, vastly more improbable that the lesions precede the presence of the parasite than that the latter exists prior to, and is the essential cause of, the lesions Koch's observations had shown that the comma bacillus was very short-lived, and they were in harmony with the observations made in cases of cholera and with the clinical history of the disease Cholera was a disease remarkable on account of the brief duration of its career, which was not longer than that of the successive generations of the comma bacillus when cultivated outside of the body Again, some striking facts had been observed by Koch in India which went to show that the parasite had been introduced into the body prior to the development of cholera Such is a synopsis of the argument made use of by Prof Flint In summing up, he said that to accept a doctrine prematurely because it was new and attractive would not be less illogical than an irrational skepticism, but while a proper sentiment of conservatism should lead us not to commit our minds unreservedly until sufficient data had accumulated to serve as a solid basis for a judicial decision, he believed it altogether probable that the decision would be in favor of the doctrines named In the discussion which followed, Dr E G Janeway expressed himself as in entire accord with the views of Dr Flint in regard to the parasitic origin of the disease

At a meeting of the New York Academy of Medicine, held in November, Dr Frank H Hamilton read a paper giving an account of the outbreak of cholera at Suspension Bridge in 1854, and also presenting his personal views in regard to our present knowledge of cholera In the first place, he said, we had no positive knowledge of the existence of a specific cholera germ, though it seemed highly probable that there really was such a germ In regard to the comma bacillus of Koch, he said that H Van Dyke Carter, of Bombay, had proved that this microbe was not infrequently wanting in cases of cholera, and that it was occasionally found in diarrhœal diseases other than cholera Again, he said, Surgeon Major Timothy Lewis, of the British Army Medical School (Netly), had found that comma like bacilli, identical in size, form, and in their reaction with aniline drugs, with those found in choleraic dejecta, were ordinarily found in the mouths of perfectly healthy persons (Dr Flint had also alluded to Mr Lewis's claim, and said in reference to it that it did not appear that the culture-test of the faucial bacilli had been resorted to, while if the statement made by him was incorrect it could not fail to be disproved by other microscopical observers) Finally, Finkler and Prior had found the comma bacillus in cholera morbus He then referred to the experiments of Rietsch and Nicati, and said he thought their conclusions should be received with hesitation, since, so far as he was aware, none of the kinds of animals claimed to have been inoculated with cholera have ever been known to contract cholera through natural sources, and it seemed to him probable that the surgical procedure adopted by these experimenters had excited an irritation in the intestinal tract which gave rise to symptoms resembling those of cholera Moreover, one of the French cholera commissions, while failing to inoculate animals by means of the comma bacillus, had succeeded in doing this by injecting into them the blood of cholera patients On the whole, therefore, it seemed to him that Koch's claims for the comma bacillus had not as yet been substantiated If, as seemed to be a fact, he went on to say, there are several microbes found in the intestines and dejecta of cholera patients, we did not know which one of these might be the active causative agent, or whether the cholera infection was not conveyed by the fluids in which they were found, rather than by the microbes themselves The theory of Koch, that the infection entered the system through the alimentary tract alone was not proven, and he believed there was good reason for supposing that it also entered by means of the respiratory organs and was diffused through the circulatory system

In the discussion which followed, Dr Francis A Delafield said he thought that at the present day all would be willing to acknowledge that cholera belonged to the class of diseases believed to be due to the agency of some specific poison The latest theory in regard to the cholera poison or germ was in accordance with the prevalent opinion of the times There are always fashions in the scientific world, which are sometimes good and sometimes bad, and the present fashion was to refer the causation of all infectious diseases to particular minute living organisms While Dr Hamilton had stated the evidence for and against this hypothesis in the case of cholera, he had not stated (a matter that it was important to have in mind), that out of quite a number of experimenters who had investigated the subject, there might in reality be only one or two whose testimony could be accepted as worthy of credence The *technique* of such investigations was exceedingly laborious and complicated, and he believed that there are extremely few individuals who are sufficiently expert in its details to be capable of making trustworthy observations As to the probable correctness or erroneousness of Koch's conclusions, Dr Delafield did not commit himself to any opinion

Dr Alfred L Loomis thought that cholera belonged to that class of infectious diseases in which the special poison is developed in a living organism, but is in a passive state when it leaves such organism, it being necessary that the agent should undergo certain changes in connection with decomposing organic matter, after leaving the body, before it is capable of giving rise to infection He believed in the existence of specific cholera germs, and that in a large percentage of cases it entered the system through the intestinal tract It remained true, however, that this sometimes occurred also through the respiratory tract, and all that one could say positively was that it undoubtedly entered the body through the mucous membrane Although all previous researches in regard to the specific germ of cholera are insignificant compared with those of Koch, he would not be willing to accept the conclusions of the latter until it could be proved beyond any question whatever that the comma bacillus was always present in cases of cholera, that it was never found in any other disease than cholera, that it was never found in the healthy body, and, finally, that inoculation with it would give rise to cholera

At the November meeting of the County Medical Association, Dr Charles A Leale read a paper on the cholera epidemic of 1866, but no reference was made to the bacillous origin of the disease At the meeting of the Association which was held December 15th, however, when there was a general discussion of the subject of cholera, Dr Janeway spoke at length of the latest researches of Koch, which had so materially strengthened his position in the eyes of scientific men

By disproving, in the most successful manner, the claims of Lewis, who thought he found the comma bacillus on the faucial mucous membrane of healthy individuals, and of Finkler and Prior, who claimed to have discovered it in cholera-morbus, and, on the other hand, by his own complete and satisfactory confirmation of the results obtained in inoculating animals by Rietsch and Nicati, Koch had now, he believed, added the "missing link" that was necessary to complete the proof, and had positively demonstrated the correctness of his views in regard to the parasitic doctrine of cholera In one point, however, he differed from Koch The latter thought that the infection always entered the system through the alimentary tract, but it seemed probable to him that it was sometimes received by means of the breath It was possible, however, he thought, that it might be carried by the breath into the mouth, and then swallowed, as he believed was undoubtedly the case sometimes in typhoid fever The President of the Association, Dr Wm Detmold, thought that while the bacillus was now the fashion, he was not satisfied that it had been proven to be the essence on which cholera depends All new discoveries, he contended, had to be sifted through a great many cool brains before they could be accepted as scientific facts Dr Flint's remarks on this occasion were mainly of a practical nature, as Dr Janeway had said all that he wished to add in regard to Koch's doctrines, and in case of a visitation of cholera he urged with great force the importance of a thorough house-to-house visitation on the part of the health authorities The past history of the disease showed, beyond the shadow of a doubt, that the disease as a rule was thoroughly amenable to treatment in the early stage, and he believed that if every family in the community could be visited every day by a sanitary inspector, and have the inquiry put to it whether any of its members were affected with diarrhœa, cholera would be divested of a very large share of its fatality

The Board of Estimate and Apportionment has added to the provisional estimate for the health department the sum of $50,000, to be used only in case the cholera comes, but when we reflect how vast would be the pecuniary loss to the city in case an epidemic should occur, it cannot fail to be seen how much better, from a monetary view, it would be that the appropriation should be used for additional sanitary work now, before the cholera comes, in order to put the city in the best possible condition in advance The Board of Health is believed, by competent judges, not to be as efficient at present as it was under the administration of Prof C G Chandler, and the reason for this is attributed to political influences Thus, for months the manure dealers maintained a notorious nuisance, but no attempt was made to interfere with it by the board until the ladies of the neighboring district of Beekman Hill appealed to the grand jury and secured the indictment of the contractor, accompanied by a reprimand to the health board In commenting upon the matter recently Prof Chandler remarked "I believe it was the action I took against those yards that lost me the presidency of the board, for the men connected with the manure business are rich and have a strong political backing "

WAVELAND, IND , NOV 14, 1884

DEAR JOURNAL —The following extract from a letter, written by a young lady to her most intimate lady friend, gives an amusing account of a consultation held in her case at Lancaster, Pa

Her physician Dr A , being in doubt, takes her into the city to consult Dr M , but the extract speaks for itself

> Just imagine me seated in one of Mr C's parlors, with Dr A on one side and Dr M on the other, both questioning at the same time, "Put out your tongue , let me feel your pulse , please look me right in the eye, no harm to look the old doctor in the face Does your back pain you much ? Your side ? Your head ? Your breast ? Allow me to hear the pulsations of your heart, no harm for the old doctor to place his ear to the *young ladies'* heart," etc , etc You would not wonder if I could not keep from laughing or crying (I did not feel particular which), weak and sick as I felt myself to be

I needn't add that they diagnosed the case and treated it successfully, but if my patients are going away to write me up in that manner I shall hereafter confine myself to essentials By the way, I have lately had an interesting experience, as a large scar that have examined this subject, none, perhaps, have attained a wider hearing than Magitot, of Paris. This gentleman published a work on this subject in 1868, in which he makes an extended examination of the subject, arriving at the conclusion that decay is caused by acids. These acids, however, are derived from the saliva through the process of ferment action. Dr. Magitot instituted a long series of experiments to determine the effects of the suspected acids on the teeth. This series of experiments shows that most of the organic acids act very feebly on the teeth in the proportion of one to one thousand of water; and that in the proportion of one to one hundred they act quite energetically; so that the teeth submitted to their action will be completely decalcified within a few weeks or months. Most of this series of experiments were continued, however, for two years. The conclusion seems to be that caries may be produced by any of the group of acids that may be developed by the fermentation of the saliva. These are the lactic, acetic, butyric, etc.

Dr. Magitot states distinctly, that the agency of micro-organisms in the production of these acids, is admitted by him; but discusses this phase of the subject no further. He makes no effort to determine to what extent these acids may be formed in the mouth. All of his experiments were tried out of the mouth, and no provision, whatever, was made to ascertain the effect that fermentation may have had on his solutions in the progress of his experimentation. This being the case, the only result of the experiments is the determination of the strength of the solutions of these different acids, necessary to decalcify a tooth.

This, together with the fact, obtained from other sources, showing that most of these acids are the products of certain fermentations that may go on in the mouth, gives much force to Dr. Magitot's conclusions.

Very soon after Dr. Magitot's work, in the same year, indeed, came the work of Lieber and Rottenstein, to which we have referred. The work seems to have been written for the express purpose of showing that decay of the teeth is caused by the life and development of the fungus known as leptothrix buccalis. In this the authors seem to have signally failed. They certainly make but little advance toward the demonstration of the parasitic theory of this affection. Indeed they do not seem to have endeavored to show that this fungus does more than promote decay that has already been established.

They say, after having made an extensive examination of the life and growth of the leptothrix, "From what has been said it results that two principal phenomena manifest themselves in the formation of dental caries, viz.: the action of acids, and the rapid development of a parasitic plant, the leptothrix buccalis."

They do not suppose the leptothrix buccalis capable in itself of attacking the teeth, if their condition be normal, but when their surfaces are once softened by acids, then the fungus may penetrate the portions thus softened, and continue the destruction.

Again they say: "It seems that the fungi are not able to penetrate an enamel of normal consistency. The dentine itself, in its normal condition of density, offers great difficulties to their entrance, and we are not yet sure that the leptothrix could triumph over this resistance." Again: "We cannot decide at present if the leptothrix is able to penetrate sound dentine, when, from any circumstance, it happens to be denuded." * * * "But, if the enamel or dentine are become less resistant at any point, through the action of acids; or if, at the surface of the dentine, a loss of substance has occurred, then the elements of the fungus can pass into the interior of the dental tissues, and produce by their extension, especially in the dentine, effects of softening and destruction much more rapid than the action of the acids alone is able to accomplish." * * * "The participation of the fungus is constant in the progress of caries which have reached this stage. As soon as a loss of substance can be shown there is found the presence of the fungus, so that the question whether or no the acids alone could produce ravages more considerable is without importance."

The modus operandi by which leptothrix may produce softening of dentine is left without explanation. We can conceive, however, that they may do something to assist the softening process by the outpouring of a digestive fluid. If, however, this fungus gave a fluid that would digest a tooth, we would think that sound teeth would be very scarce, for it grows abundantly in every mouth.

Since the time of Lieber and Rottenstein's work we remember of no other of much importance having appeared on this subject. The discussion has continued, however, in the journals. We cannot undertake to review this literature, interesting as it would be; but we must content ourselves with one writer, Dr. Miller, now of Berlin.

Dr. Miller's experiments bear the stamp of being more carefully performed than any that have previously come to our knowledge. This was have been expected from the fact that they are the latest, giving the experimenter the advantage of all that has gone before, and for the reason that he is very favorably placed for such work, being in the midst of the best experimenters of the world. Therefore his work is looked to with unusual interest.

We need not, however, notice any but his last series of articles, that which is now appearing. We cannot, of course, criticise Dr. M.'s work now, for we have not heard him through; but enough has appeared to show very clearly what the result will be.

Dr. M. begins this series of articles with this sentence: "During the last two years I have stated at different times and places, as the result of many experiments, that 'the first stages of dental caries consists in a decalcification of the tissues of the teeth by acids, which are for the greater part generated in the mouth by fermentation. The object of the investigations described in this and the following papers is to determine this ferment, and the conditions essential to its action.'"

We see from this that Dr. Miller begins just where Dr. Magitot left off, sixteen years ago. The discussion of the subject during these years has given us no additional facts as to the essential nature of these phenomena, but the advance of thought in reference to the general subject of such investigations has been such that no man would now repeat Dr Magitot's course of experimentation with the same end in view

I will give you a very brief synopsis of Dr M 's course And while I do so I wish you to keep in mind the object he has in view It is admitted that decay is brought about by acids, developed, or Dr M supposes them to be developed, by fermentation of some kind The object of this course of experiments is to find and examine this supposed ferment

It is not necessary that I should describe in detail all the apparatus with which the experimenter provided himself, it is sufficient to say that all the appliances for the prevention of error were used The first question to determine was whether or not the ptyaline of the saliva could so change starch as to produce an acid This question was soon decided in the negative The starch was promptly changed into sugar, but here the reaction ceased, the fluid remained permanently sweet when the proper precautions were observed to prevent the ingress of germs This proves that the acidifying power does not belong to the saliva It must, then, be something foreign

Now, a freshly extracted carious tooth was taken, all food removed, the outer portions of the decayed mass saturated with a 90 per cent solution of carbolic acid to destroy any accidental germs that might be in this portion Then, with an instrument, purified by heat after each cut, layer after layer of the softened dentine was removed until the inner portions were reached Then a slice was quickly conveyed to a sterilized culture medium, composed of sterilized saliva, water, sugar and starch, and placed in an incubator, together with another test tube of the same culture fluid uninfected, to serve as a check In twenty-four hours the infected culture became acid, while the other did not This remained constant in a sufficient number of experiments to establish the fact that the acidity was due to the infection

From the cultures that had become acid, other cultures were infected, which also became acid, thus proving that the experimenter was dealing with a ferment that was capable of propagating itself, an organized ferment

Microscopic examination showed that these cultures contained an organism similar to those found in the deeper layers of carious dentine, and which remained constant in their characters Chemical examination which seems to have been carefully conducted, showed the acid produced to be lactic acid This acid has been shown to be capable of decomposing the teeth by M Magitot, and many others Yet Dr Miller goes still further, and by placing sections of dentine in his culture fluids that he has infected, finds that they are decomposed by the acid formed, while such sections placed in such fluids not infected are not changed Thus he not only proves that an acid is formed, but that the acid is formed in sufficient amount to destroy the dentine

This, when compared with the best experimentation previously had, marks a great advance One point seems to have been gained One organism has been traced thus far, and may now be said to have been proven to be able to produce certain of the phenomena of decay But this is not all There is much yet to be done True, one other point is spoken of by Dr Miller All who have made a careful study of caries know that there is a peculiar enlargement of the tubules, which is not seen in dentine softened by acids alone Dr Miller has been looking for this also, and not without success, for in some sections of dentine exposed to the action of the cultures, he found the organisms crowding into the tubules, and tells us that he also found them enlarged as in natural caries of the teeth in the mouth, indeed that he had before him veritable caries, artificially produced

This delineation of results of experimentation must have great weight in the settling of the problems at issue, especially if they are confirmed by other competent observers There is nothing in these experiments that is not in harmony with known facts, unless it be the widening of the tubules by the crowding in of the organisms It is known by previous experiment that this widening is not caused by the lactic acid as it exists dissolved in the surrounding medium, and I think very few will be willing to concede that the organisms can accomplish this by physical force This point requires further investigation, and its study will doubtless lead to further discoveries However, I think it may be explained in advance, at least the effort may serve to direct experimentation

In a previous lecture I have dwelt at some length upon the digestive fluids of living organisms Unexpectedly I find use for these ideas now, for they were written before I saw Dr M 's last article I have explained how it is that dead bone, roots of the temporary teeth, ivory driven into the flesh, catgut ligatures, sponge, etc , are dissolved and removed by a soluble ferment I have also shown that the soluble ferment of the yeast plant has been found and proven Also that of ammoniacal fermentation, and how plants take up otherwise insoluble substances Now, this widening of the tubules is a conceded fact It is also shown that it is not done by the lactic acid in case of other experiments, nor can it be done by the physical force of the organisms, but it can, in all probability, be done by the digestive fluid of the organism The conditions for this work of the digestive fluid are the same as that of the granulations in widening the meshes of the sponge and finally removing the last of it As yet no soluble ferment has been demonstrated in connection with this organism, but theoretically it must exist, and if Dr Miller should undertake to search for it, he will be able to demonstrate it speedily, and determine its cooporation in producing some of the phenomena of decay, at least determine its capabilities This organism cannot be said to have been definitely and completely studied until this soluble ferment, or diastase, be found, isolated, and its capabilities separately determined (Since the above was written Dr Miller has reported the finding of this soluble ferment)

It is by no means probable that this is the only organism that may stand in a causative relation to caries (Since the above was written, Dr Miller has also reported the finding of another micro organism that he thinks capable of producing caries)

The organism of butyric fermentation, possibly that of acetic fermentation, and a large number of others of the acid fermentations, may cause decay, nor is it by any means a settled fact that decay of the teeth may not be brought about in part by other vital processes than the acid fermentations Of this, however, we will speak later

Another question may arise in this matter and need explanation I have repeatedly said that the waste products of an organism prevented the activity of that organism when collected in a certain amount How then can this organism continue to thrive in its own waste product, and thus continuously promote caries, by furnishing more, and still more, of this waste product? Simple enough Every chemist who has studied lactic fermentation has been in the habit of introducing some form of lime into the fermenting fluid to "fix" the lactic acid in the form of a lactate of lime, in which case it does not hinder the progress of the fermentation In this way a much larger amount of the lactic acid may be obtained, as it is readily regained from its salts This was learned long before this organism was found Now, in the production of caries, the tooth presents the lime for the formation of the lactate, and thus furnishes the very conditions necessary to the continuous growth of the organism

I wish now to turn your attention for a moment to another class of phenomena, and make some inquiry into their possible participation in the production of caries I have already spoken of the strong probability that the otherwise normal tissues, when under the influence of certain qualities of inflammation, emit a fluid of acrid and very irritating properties About the necks and other parts of children we sometimes see this fluid excoriating the skin wherever it touches it, seemingly acting the part of a caustic I have already referred to the fact that dead bone, ivory driven into the flesh, sponge, catgut ligatures, etc , are dissolved and removed This causes us to inquire whether or not a substance may be elaborated in the same manner in the mouth, that may have its quota of effect in the production of the phenomena of caries

I was thoroughly convinced that this was the case years ago, though I endeavored to explain the results by the assumption that an acid was formed This is entirely unnecessary Soluble ferments do not seem to depend for their action on either acidity or alkalinity They seem to be controlled by some other than the known chemical laws, and their action is not yet understood We have no means of explaining them If a piece of ivory thrust into the flesh is attacked and burrowed out in holes by a secretion thrown out by virtue of the irritation induced, as asserted by Krause, Keoliker, and other of the most capable observers of the world, why may not a tooth be attacked in the same way by virtue of an irritation of the tissues about the neck, or during the irritation consequent upon its eruption when this is unusually prolonged? As a matter of fact, it has been observed that decays are prone to occur in just such situations as tend to confirm this hypothesis

Thirteen years ago we drew attention to this, in a paper before the Illinois State Dental Society Both before and since that time I have given much attention to this point, and I am more than ever convinced that it has much to do with the beginnings of decay I do not wish to be misunderstood in this matter It is not my notion that decays are initiated by this cause alone It is only one of the first steps by which other forces which come later are rendered operative —a means, if you please, by which the surface of the tooth is first broken, and by which organisms are permitted to find lodgment, not a means by which decay is carried on, to the complete destruction of the tooth This effect cannot be produced except while the tissues are in contact, or in very close proximity to the part in the process of solution, for the reason that the secretion from the tissues would be dissipated in the fluids of the mouth before they could have time to produce their effects upon the tooth's structure

The positions at which these results are seen, are Wisdom teeth, that come through very slowly, on the buccal surfaces of the molars generally, and sometimes on the labial surfaces of the upper incisors In case of the wisdom teeth, the fact that they are very often decayed before they are fully through the gum is especially remarked, and as a rule, if these decays are carefully noted at a very early period of their progress, it will be seen that they are different from other decays in several respects It always has its beginning under the free margin of the gum There is usually no change whatever in the appearance of the tooth, the eye discovers nothing The surface seems normal, or at most the portion of the tooth appears rather whitish, but on trial with the excavator the instrument will apparently break in through the enamel prisms, disclosing a cavity of very slight depth It often happens that the enamel may be easily scraped away over a considerable space, as though it was so much chalk The depth will present much variation, often it is only a part of the thickness of the enamel, at other times we may find it extending into the dentine, in which it forms a veritable cavity If there is much depth, however, the characteristics will have assumed the more usual type

Occasionally we see this character of decay (if it may be so called) in the grinding surfaces of the wisdom teeth, occasionally in the first molar, also, where the tooth has come through very slowly, and the gum has been for a long time in a state of chronic irritation

It is characteristic of this effect that it is as often seen on the smooth surfaces of the teeth as in the pits and grooves No imperfection is necessary to prepare the way for this manifestation

As I have said this takes place under the gum, is covered by the gum Now as the tooth rises higher and the surface thus affected becomes exposed, these spots are prone to become the seat of true caries with all of its usual manifestations However, very often caries does not take place In this case, a whitish spot is seen, which gradually assumes a yellowish tinge, then brownish, and finally becomes black This result is brought about by the settling into, or the formation in, the affected tissue of the black sulphurets, as I was the first to show (See report on dental chemistry, by Dr H A Smith, Transactions of the American Dental Association, 1874, page 78)

We see these spots every day upon the sides of the molars in every stage of coloration, from ashy white to a deep black They are as apt to be on the otherwise smooth surfaces as in the pits and grooves They may occur on any of the teeth, but are oftenest seen *in the position named The decays that so often* occur on the labial surfaces of the upper incisors, are often, though not uniformly, of the same character

Those decays that occur just at the junction of the enamel and cementum, in persons of middle age or past, occasionally in younger persons, seem, in very many cases, to be of the same character Some irritation of the gum at the immediate spot seems to be one condition of their beginning These also have some special characteristics not common to other decays If they are closely examined very early in their inception, it will be found that the cementum has been removed, and that the margin of the enamel has become chalky, soon after this, if the case continue to progress, the gum, which till now was closely applied to the part, becomes everted so as to expose the breach in the tooth This often becomes the seat of the most exquisite sensitiveness just at the present stage of the process, which calls the attention of the patient to the spot Generally, however, nothing can be seen by either patient or operator, except a slight evertion of the gum, and the slight grooved appearance of the neck of the tooth, which the operator is often puzzled to differentiate from the normal form of the tooth However, if he will carefully press the gum away (and he will find this abnormally sensitive) until he can see the root of the tooth below plainly, it will be easy to demonstrate that there has been a decided loss of substance Trial with an instrument will develop the fact that the surface within this groove is exceedingly sensitive, the dentine is exposed Now if the case is left to itself, this sensitiveness will continue for some weeks, or even months, and then abate, and it will be found that the case has taken on the usual character of decay It may cease to progress and assume a dark color, or it may progress rapidly, and remain of a more or less ashey cast

It has been our opinion that this class of decays, if that term can be applied at this stage, is brought about in precisely the same way that the root of a permanent tooth is partially absorbed on account of a chronic irritation of its peridental membrane In other words a soluble ferment has been called out by the irritation, that has dissolved out a part of the tissue at that point Or, if you prefer to have it put in that way, a true absorption has taken place which forms the nidus for the future decay

Another class of decays are very common which I have studied very closely, and which seem to be of the same character in their inception These begin under the free margin of the gum under plates that abut closely against the teeth These are usually very rapid in their course, evidently for the reason that as soon as the free margin of the gum is everted a pocket is formed by aid of the plate, in which fermentation can proceed to the very best advantage It does not seem that the beginning of this decay is often after the evertion of the gum has uncovered the spot Of course, we often see decays occur where clasps encircle the teeth that are high up on the crown Such must not be confounded with those that begin at the margin of the cementum

DISCUSSION ON DR BLACK'S PAPER

Dr Marshall —In Dr Miller's experiments on dental caries, whether produced in the mouth or artificially in his culture fluids, he invariably found an enlargement of the dental tubuli, to the extent of the penetration of the affection, and that the tubuli were filled with micro organisms

Dr Boedecker, of New York, found the same enlargement of the tubuli, but minus the micro organisms, in his experiments with regard to the action of arsenous acid upon healthy dental tissue

Dr Black refers the cause of the enlargement in Dr Miller's experiments under both conditions, to the action of a soluble ferment produced as a waste product by the *bacterium lactis*, and which dissolves or digests the organic portion of the tubuli, and the inorganic material surrounding it, while Dr Boedecker refers the condition found in his experiments to inflammatory action resulting in absorption caused by the irritation of the arsenous acid

I would like to ask Dr Black whether he considers the conditions found by these gentlemen to be identical?

Dr Black —I will first say that I do not regard the results as caused in both instances by the *bacterium lactis*, but in both cases the results are brought about, in all probability, by a digestive body The action in both cases is the same in kind, the philosophy of the widening is the same in both instances, the difference being that the digestive bodies that do the work are produced by different forms of life In the case of Dr Boedecker's experiments, the conditions described could only be due to the formation by the irritated dentinal fibrils of a menstruum which digests and removes the tubular wall

In Dr Miller's experiments, the bacteria form a menstruum which digests and removes the walls of the tubuli

In the case of the *bacterium lactis*, a digestive body, or diastase, has now been demonstrated by Dr Miller, the organism is fully proven to be able to perform the act of digestion, and we know that the tissues of the higher animals have the power of removing parts by what is usually called absorption, and which is a form of digestion

It has been well shown that the pulp chamber may be enlarged in this way in cases of long-continued irritation of the pulp Bone is also easily removed under pressure, evidently by a similar vital process—a process of digestion by means of a digestive body

Dr Allport —Dr Boedecker's experiments with arsenic upon dentinal tissue (though not yet fully completed) were upon living tissue, and evidently prove that there was inflammatory action set up in the tubules, causing absorption of material Dr Miller's experiments were upon dead tissue (teeth out of the mouth), and the action seems to have been a chemical one In the first, the process was a vital one, and may be in kind like that manifested in the absorption of the roots of deciduous teeth, the removed material being largely taken into the general circulation, which may have been "re-molecularized" and converted into new tissue, or carried off as a waste product

While, in the other case, the action was entirely from without, and would seem to have been from acids, and independent of vital processes within the tissues I can imagine how micro-organisms may produce a sufficiently exalted irritation of the dentinal fibres to cause absorption of material similar to that produced by the irritation of arsenic in the experiments of Dr Boedecker

But in either of these conditions I should expect the changed material would be largely carried off in the general circulation, the same as it is in the enlargement of the pulp cavity consequent upon continued irritation of the pulp, as suggested by Dr Black, or the absorption of the roots of the deciduous teeth, in both cases the organic and inorganic materials are removed entire, while in caries occurring in the mouth the inorganic material only is largely removed, the organic portion remaining behind to die, be decomposed and washed away, or pass off in gases

In the experiments of Dr Miller the conditions are entirely external, and a purely chemical action, resulting in a simple change of the elements, and their removal consequent upon the affinity of lime for acids Whether the fungi excrete an acid or not (and more than likely they do) is of no material consequence so long as the acid is found there, it is the affinity of lime for acids, no matter how produced, whether from a decomposition of foreign matter, or excreted by the fungi that, to my mind, produces the changed condition in the devitalized dentine

I have, of course, been much interested in the arguments of Drs Black and Miller They are highly interesting, and there is little doubt that we are approaching a correct solution of this vexed question, but it will be well for us to pause before we pronounce too confidently that either of these gentlemen accounts for all the phenomena of dental caries

Dr Williams —May not the enlargement of the tubules be caused by the physical force of the micro-organisms exerted upon the walls of the tubules? In the vegetable kingdom such instances are not of rare occurrence, rocks have been split, and large masses of solid material moved by the continued pressure of fungous growths

Dr Fredericks —Mills and Underwood first called attention to the enlargement of the dentinal tubuli, and they presented microscopical specimens to substantiate their views Dr Boedecker's experiments do not prove anything I would not put much reliance upon the observations of two experimenters I think we are begging the question

Some observers can see whatever they desire to see, and later their observations are proved to be worthless May not the enlarged appearance of the tubuli be due to the methods used in preparing the slides?

Dr Allport —I would suggest that Dr I L Susserott, of Chambersburg, Pa, be invited to speak upon this subject

Dr Susserott —I am certainly very much pleased with the paper just read by Dr Black, it proves the truth of the lines by Butler, that

> "Large fleas have little fleas,
> And these have fleas to bite 'em,
> And there are fleas to feed on these,
> And so *ad infinitum*"

Various remedies have been introduced for the antiseptic treatment of surgical diseases, the most potent of which is bichloride of mercury As used in general surgery, a solution of 1 to 1,000 is perfectly harmless, and I do not see why it might not be used with safety and success in the treatment of dental caries

Dr Harlan —The bacillus anthrax and the bacillus tuberculosis can live in absolute alcohol, and also in a 5 per cent solution of chloride of zinc

In order to know how to destroy micro-organisms we must study the individual organism, and apply the special agent which will destroy their vitality

Eugenol—in the strength of 1 in 75,000, will destroy bacteria, and a weak solution will prevent the development of the spores

Dr Black —I quoted an expression of Dr Miller's saying it was unfortunate, viz "the first stages of dental caries consists in a decalcification of the tissues of the teeth by acids, which are for the greater part generated in the mouth by fermentation" This is the same question discussed of old, of who led the pig to market, the man or the string The string is the means used by the man, and the acid is the means used by the micro-organisms, but the acid can no more cause decay, or even exist in that position, without the organisms than the string can exist, and lead the pig without the man

The micro organisms that produce caries must have free oxygen Therefore, if you plug a tooth perfectly over a little softened dentine you exclude the free oxygen and destroy the organisms It is possible, of course, that an organism not requiring free oxygen might produce caries, but all evidence we have is against that supposition

Dr Fredrich—It seems to me we are still begging the question What is the need of antiseptic treatment of caries if micro organisms cannot exist without free oxygen? When a cavity of decay is hermetically sealed no oxygen can enter, and consequently micro organisms cannot develop

Dr Marshall—It has been proved by Pasteur that there are certain forms of micro organisms that exist without free oxygen, in fact can not develop in that medium, and it is not at all improbable that such micro-organisms may exist as factors in the cause of secondary caries

Dr Black closed the discussion by saying We must come to the point of finding specific micro-organisms A poison for one form is not necessarily a poison for another Only about 17 per cent of alcohol can be produced by the yeast plant, because the excretory product of the plant—alcohol—in that degree of concentration becomes a poison to the plant and prevents further growth This same alcohol, however, is the natural food of the mycoderma aceti This plant produces acetic acid, which in turn will stop the growth of its plant at a certain degree of concentration This will now become the food of other organisms So it is, that that which is poisonous to the one is not necessarily poisonous to another Certain diseases occur in the child that do not occur in the adult We believe some of these diseases are produced by micro organisms There is some difference in the nature of the tissues or fluids in the two cases that renders the adult unfavorable soil for the growth of these organisms This gives some hope that in the continuous round of research some means may be found of antagonizing micro-organisms without a resort to poisons, as is now done These will certainly be different for different organisms

On motion it was agreed that owing to the lateness of the hour the reading of the paper by Dr Harlan be deferred, and that it be the first order of business at the session to morrow

The Section then adjourned

FRAGMENTARY COMMENTS ON SOME OF THE PRINCIPAL METHODS OF OPERATION FOR "STONE IN THE BLADDER"

With Special Reference to Allarton's Method, Also in Combination with Lithotripsy, Urethro-Lithotripsy, Urethrotomia Lithotriptica, Including Besides Critical Remarks Upon the Discussion of the Progress Made in Lithotripsy and "Lithotomy" at the Late International Medical Congress held in London, England, and divers other subjects comprising the Urinary Organs

BY M SCHUPPERT, M D , OF NEW ORLEANS, LA

(CONCLUDED)

Spasmodic Strictures, or Spasms of the Urethra —When the bladder is to be sounded we meet occasionally with contractions, or spasms of the urethra, in the introduction of the bougie, causing great difficulty in the free motion of the instrument Singular as it may appear, it is nevertheless true that the existence of such a spasmodic condition has been, and is still, denied by a great many surgeons Since John Hunter first called attention to that phenomenon, most all authors on surgery, though they might have mentioned the subject, still kept silence Their own knowledge was either very limited or they had none at all It is indeed rare to meet with an author who has observed these spasms in more than one or another case, and it seems as if their mere mentioning of them was more for the purpose of showing that they were not ignorant of the pretended existence of such strictures Brodie, Guthrie, Dittel, Bardeleben, Koenig and others belong to that class Roser, in his surgical anatomy, calls them "a thing about which much could be said " He evidently keeps "on the fence," to use a vulgar expression, as the safe side to escape a responsible position Sir H Thompson, the "great lithotomist," evidently crowns ignorance in calling such spasmodic strictures of the urethra "*a materia peccans*"—"*a refugium incompetenciæ* "—"an excuse used to cover one's own want of skillfulness to enter a catheter into the bladder " Not quite so rash, Mr Thompson ! Among the few authors I have met with, who do not treat these spasms as doubtful accidents, are the late C Hueter and Esmarch, of Kiel, of blood-saving fame The latter declares to have experienced such spasmodic strictures "dozens of times almost every year " Indeed, what a very nervous people these inhabitants of Kiel and surroundings must be I myself have during my practice here met with those spasmodic strictures of the urethra in but few instances, that is, of such spasms as caused a real obstruction to the entering catheter or bougie, and which might have been taken for strictures of an organic nature, whilst contractions of a short standing, I have more frequently met with They are also caused in a small degree by the application of the galvanic current, which, moreover, is an evident proof of the existence of muscular fibres in the urethra, though equally denied by a good many surgeons It is hard to believe, though nevertheless a fact, that a great number of anatomists, besides surgeons, up to this day are still in doubt about the existence of such muscular elements in the urethra The bladder, no doubt, is a muscular sac, surrounded by muscles, as for instance, the mighty detrusor The prostate is furthermore a muscular ring, a sphincter, and both detrusor and sphincter are, according to Henle, in *a constant active tonic condition* Might we then not, and very properly, question why the balance of the urethra should be so entirely bare of all muscular elements? It may be difficult to dissect the urethral muscle, a continuation of the prostatic ring, but that it exists and causes the spasmodic contraction of the urethra, and mostly so at the pars membranacea, aside of the compressor urethræ, cannot be doubted for a moment Muscular fibres, and strong ones besides, do exist here, the many denials to the contrary, notwithstanding Most all anatomists admit one thing that the space between the two layers of the deep pærineal fascia, the fascia pærinei propria, or capsula-pelvis urethralis, after Luschka, contains sufficient muscular fibres We have then to admit two small, flat muscles extended between the ramus ischio-pubicos, of which one, the *compressor urethræ Guthrie's*, is situated *above* the urethra, while the other, the *constrictor isthmi urethræ*, lies *beneath* that organ (to both of which muscles Guthrie has applied the name "*compressor urethræ*") By the activity of both muscles the urethra is compressed, and if an instrument is introduced, it will be held firmly, or if by a reflex action from the sensitive nerves, those muscles should be called into action, spasms may be produced, resisting the introduction of the instrument and resembling the existence of organic strictures Such happens mostly at the pars membranacea These reflex spasms of the m compressor urethræ are involuntary, beyond the control of the patient's will *Wilson* named the muscular fibres surrounding the pars membranacea, the *m pubo urethralis* *Amussat* gave them the name *pars muscularis urethræ*, and *Krause* described them as *circular fibres* Here then at least are some noted anatomists refusing to plead "a general denial "

The surgeon, in entering a bougie or catheter, ought to take into consideration the disposition of his patient If of a nervous temperament, and one who probably never had an instrument in his urethra, in such a person the irritability of his urethral nerves may be so exorbitant that at every minute he will grasp at the instrument It is an involuntary, irrepressible conflict, in which the will becomes totally routed In such a case the surgeon has to use the utmost care to establish the diagnosis, and avoid being too hasty in predicting the presence of organic strictures In meeting with such an obstacle any and every force to penetrate with the instrument any further is to be interdicted, because pain and the spasms would thereby only be increased, and a laceration or a false passage be established Under a weak but steady power, holding patiently the point of the instrument against the stricture, the spasms in most instances will soon subside, and the resistance disappear In such nervous subjects a subcutaneous injection of morphia is best applied previous to another introduction of the instrument Ice applications to the pærineum may also be of service In some cases, and mostly so in irritable children, narcotization with chloroform may even become necessary

There are cases on record where death has even resulted from the introduction of a catheter, and more frequently do symptoms happen resembling the algid stage of an intermittent fever, which very improperly has been called "*urethral fever*," though no rising of the temperature happens

All these are proofs how careful the surgeon has to be in meeting with such persons, and where he is obliged to enter an instrument into the urethra The mischief ignorance and stupidity may cause in spasmodic strictures, principally consists in the establishment of *false passages* I have had ample opportunity to become acquainted with such lamentable proofs of malpractice What surgeon, even of a limited practice and experience, who, if he has not had the misfortune to cause a false passage himself, will not have met occasionally with such proofs of unskillfulness? And who, in falling in with one or another of such cases, will not have become aware of the difficulty of introducing the catheter, and the more so if, in his manipulations, he should meet with the simultaneous presence of spasmodic strictures? Such obstructions, often seemingly insuperable, suffer hardly any comparison with any other obstacles existing in a surgical operation They offer a condition wherein the greatest patience, endurance and perseverance are demanded Very properly, therefore, said one of England's greatest surgeons, Liston "The operation of introducing a catheter through what has been called an impermeable stricture, is, without doubt, the most difficult in the whole range of surgical operations, and demands all the prudence, science and skill of a master " And what of that difficulty and mastership if such a case should be associated with one or more false passages? Spasmodic strictures may happen in the urethral channel as far as muscular fibres extend If a metallic bougie is introduced into the urethra, replenishing its lumen, so that the walls are in close contact with the metal to which the positive pole of a galvanic battery (of about ten elements, Daniels) is attached, while the negative pole is placed somewhere on the body of the person, the bougie thus located in the urethra will after awhile be held so firmly that its removal without causing any injury to the mucous membrane of the urethra can only be accomplished, and in an easy manner, by exchanging the poles of the battery, attaching the negative pole to the bougie where the positive one had been before, producing the tight grasp of the contracting muscles of the urethra The degree of contraction increases the further the point of the bougie is pushed towards the bladder, or with the increase of muscular fibres, while the contraction becomes weaker toward the meatus and ceases totally just behind the glans penis

Without the presence of muscular elements that phenomenon would be unaccountable In view of the opposition which here exists, the total denial of the existence of muscular fibres in the urethra, it must, indeed, look strange that no author has ever mentioned this phenomenon, and the more so since the galvanic current there exist still other means to arouse the contractility of the muscular elements If a "*sound, a double courant*" occupies the urethra and a stream of ice cold water runs through the instrument for the space of ten or fifteen minutes, the sound will also be grasped, and so tightly, that it requires some care and time to retract it without causing injury to the organ And the degree of contraction corresponds here also with the length of the urethra occupied by the sound or the increase of muscular fibres towards the bladder

The Urine —Though a great deal has already been said of that liquid, still its importance may well deserve a special chapter

In all operations comprising the urinary tract, the dogma of the noxious action of the urine, when coming in contact with wounds has played and still plays an important role Most all surgeons are endeavoring to find means and ways to get rid of that, to them, almost unexceptionally dangerous material. Proofs of that *ignis fatuus*, the urine, if coming in contact with a wound can be met with in the works of many authors, especially gynæcologists Thus *Wutzer*, of *radical cure of hernia* fame, in operating for vesico-vaginal fistula perforated the bladder above the symphysis pubis, torturing his patients by confining them on knees and elbows during twelve days, for the sure and constant removal of that same inimical liquid, the urine, to obtain, finally, after a dozen unsuccessful operations, and some cuticular gangrene on the knees of his patients, a complete failure But at a much later period, and most conspicuously, could that fear of the urine be observed by Simm's invention of a self-retaining catheter, to keep the bladder constantly empty and the wound protected against that noxious liquid, the urine The real action of the urine on one side, and the existing confusion and ignorance on the other, call, therefore, for some further elucidation

It has been asserted that urine coming in contact with incised wounds, would prevent union by first intention It has also been admitted that urine, by infiltrating the tissues of incised or lacerated wounds, would produce necrosis and gangrene, and by infiltrating the pelvic cellular tissues cause even the death of the patient Such, at least, was the generally admitted dogma, till the late Prof G Simon, of Heidelberg, Germany, in 1862 published his experiments, in which he proved that the sweeping assertions of the noxious effects of urine had no foundation of fact on which to rest Simon showed in an incontrovertible manner that urine of an acid reaction was an entirely innocent liquid, and that only to an alkaline urine, or one in a state of decomposition, the noxious influences could be attributed Simon established further, by numerous tests, that it required from five to ten days before an acid urine having been in contact with living animal tissues would turn alkaline, and that an acid urine, though having been in contact with dead animal matter, or having stagnated for some time in the living subcutaneous cellular tissues, did not became pernicious to that tissue as long as it retained its acidity On the contrary, it seemed rather as if such acid urine, probably by its saline constituents, acted more as a preservative Necrosis and gangrene of the tissues, so often observed in penetrating wounds of the urinary organs, of the bladder, or urethra, when a great quantity of an acid urine had infiltrated the tissues, could not be explained as a chemical, but as a mere mechanical action of the urine In such an action the blood vessels nourishing those parts would be compressed or lacerated, in consequence of which gangrene might set in The faulty interpretation of these facts mainly caused the fable of the pernicious property of the urine The same extensive gangrenous destruction might be brought on by using large quantities of pure water, if only a certain pressure on the nourishing blood vessels could for some time be maintained by them

Unaware of the experiments of Simon, I had called the attention of the profession to the innocuousness of a healthy normal urine It so happened that in the treatment of a case of vesico-vaginal fistula, I was forced by circumstances to relinquish the seemingly well established rule of the after treatment, to retain a catheter in the bladder Again disregarding that rule in the next operation, to find out if it had been a lucky accident, or if the use of the catheter could be dispensed with without injuring the result of the operation, it became with me the rule, instead of the exception, to dispense with that most annoying part of the treatment—the retaining of the catheter The experiments of Simon, which meanwhile had come to my knowledge, taught me the reason why, and from that time I took the precaution to operate only in the presence of an acid urine, and obtain the same success as formerly under the old rules of the protecting catheter [1]

The investigations and experiments of Simon have been of the greatest importance in the operation of cystotomy, in fact, wherever an alkaline urine may come in contact with wounds of the urinary tract The urine ought, therefore, always to be examined previously to an operation on those parts, and no operation ought to be undertaken before that liquid has been made acid It is then that the most scrupulous and thorough methodical antisepsis be employed by irrigation of the bladder and urethra with 3 per cent phenol water Many an operation with a probably fatal exitus would, under an observation of this important rule, meet an entirely different issue

Bigelow, in the description of his method, has not given any special preparatory treatment It is only after the operation that he wants the bladder to be washed out with "mild antiseptics" But whenever antiseptics are required, it will certainly be inopportune to use them in a '*mild form*" In a wound of the urinary tract phenol water of at least 2½ to 3 per cent ought to be freely and frequently used, especially in the presence of decomposed or alkaline urine, where the latter could not first be made acid Bigelow himself states that "The deep urethra be even less tolerant to injuries, and that he had even lost four such cases by death" The wound of an organ which, under the scrupulous attention here given, promises almost absolute security against any serious or fatal issue! But if Bigelow thinks that "strips of the mucous membrane of the bladder might be turned off with immunity," he will be greatly mistaken in case any of those fearful complications as a "surgical kidney" or chronic cystitis, or an alkalinity of the urine even, should be present The important question about the chemical composition of the urine, as well as the danger arising from the setting free of certain micro organisms enclosed in a stone by even the least lithotriptic efforts, seemed to have entirely escaped him All that Bigelow has to say about that important liquid, the urine, is that "a most troublesome condition to be met with consisted in the presence of a certain mucous substance causing tenesmus, and which could not pass through the catheter"

Chronic Cystitis —This dreadful disease has already been mentioned on several occasions, associated with and without a simultaneous affection of the kidneys, as pyelonephritis, etc It happens more frequently in people of an advanced age, with and without the presence of a calculus It is a very resisting evil and is accompanied with a good deal of pain In most cases there exists an enormous increase of the prostate, sometimes with retention of urine The latter is muddy, and of neutral, or oftener of an alkaline reaction, and the patient has a constant desire to empty the bladder, but with an inability of discharging its contents The best method of treatment here consists in frequent introductions of large metallic catheters every three or four hours and injections of warm water containing one-half per cent to one per cent of sulphate of zinc, of a weak solution of acetate of lead, or frequent irrigations with 3 per cent phenol water, also the internal use of an alkaline mineral water

---

[1] Simon, in an essay of his alluding to a publication of mine, called me "the only representative American who had dispensed with the catheter but at the same time considered it strange that I (at that time) still hesitated to give that instrument up for good Simon was misled by a statement which had only reference to a special case It was evident that he had mistaken the sense of the statement still I did not consider it of sufficient importance to correct the error into which he had fallen

The strictures which are observed, are frequently of a spasmodic character, without the least sign of an existing inflammation But chronic cystitis may also be complicated with real and constant strictures of the urethra In such cases I have observed external urethrotomy (Boutonniere), with a subsequent introduction of a short, straight metallic catheter kept in the bladder for some time, of great value, yet I hardly think that a better treatment could be selected I have performed the "Boutonniere" sixteen times, and in some of the cases had as many as six and eight strictures, accompanied with abscesses and fistulas, on and around the scrotum In several of these cases hardly the finest bougies could be passed through the urethra In one of these cases there were eight abscesses with four fistulas, comprising the scrotum and its surrounding parts What influence an incision into the urethra exercised upon the dilatation of that organ could be experienced here by entering the largest bougies, where previously only the smallest were with difficulty introduced In some cases the metallic catheter was retained six weeks till the last fistula had healed Where of late, irrigations with phenol water were frequently used, I in former times was in the habit of injecting and washing out the bladder with chamomile infusions, adding borax or benzoic acid, and occasionally in aggravated cases a strong solution of nitrate of silver 1 to 8 Serious as some of the sixteen cases had been, not a single one was lost by death [1]

Renal Calculi Passing Through an Ureter —The most dangerous and pain-causing renal calculi are those which, be it by their large size, form, or shape, in passing through one or another of the ureters become arrested there or implanted They may lacerate the mucous membrane, causing inflammation, abscesses, and produce symptoms resembling the most intense, violent colic Such an abscess may, in breaking through the wall of the ureter, discharge its pus into the abdominal cavity and cause death under the symptoms of marasmus, a case of which I once witnessed Such renal calculi may also be arrested in the urethra, produce a local inflammation with its sequelæ, involving even the cellular tissues of the scrotum and the penis

I once observed such a calculus passing through the left ureter of a woman, and which passage lasted three weeks, causing an almost constant but moderate "colic," which of course did not yield to medication The woman being pregnant at the time, the pain was first wrongly interpreted Nevertheless, suspicion being aroused, I ordered her to yield her urine exclusively in the urinal and pay attention if no stone should come away One day she heard some hard substance drop into the vessel, which proved to be a smooth, oblong renal calculus, measuring 10 mm in length and 6 mm in width From the time of the stone's discharge all pain subsided Small as the channel of an ureter is, its muscular fibres are, like those of the urethra, of great extensibility and powerful contractility, ejecting the urine with a great force at times In two cases of vesico-vaginal fistulas with an everted bladder, I observed the urine to be discharged alternately from both ureters in solid streams and at considerable distances

A three years old boy was one day brought into my office suffering from enuresis and intense pain in his over extended bladder, while his mother stated that previously the boy had suffered from "a mighty pain" in his left side, which had lasted over a week Entering a catheter into the meatus urethræ, I met with a hard substance behind the glans penis, well implanted in the mucous membrane Removed with a small metallic earspoon, it turned out to be a renal calculus of uric acid The urine was muddy, alkaline, and contained pus Some blood followed the extraction of the calculus I injected a 3 per cent solution of phenol into the bladder and urethra, ordering the latter to be washed out frequently No serious consequences followed I place some weight upon this, because I saw another such case where the calculus had perforated the urethra after obstructing the same for some time, and where no antiseptics had been used, ending fatally The history of the boy's ailment, first given, left no doubt that here again a renal calculus had been temporarily arrested in its left ureter, and finally had become implanted in the passage through the bladder in the urethra, where, forming an abscess, it would soon have perforated the urethra By the constant irritation the calculus had caused in the urethra, the boy had fallen into the habit of pulling the prepuce to a length of 4 ctm (1½″), which called for circumcision

One of the greatest agonies and sufferings I ever have observed was in a man of forty, with a calculus implanted in his left ureter (Was it but accident that all the cases which came under my observations happened in the left ureter?) At several times on entering his room I found him lying on the floor, which showed the impression of his finger nails That painful condition lasted five days, during which time he had almost constantly to be kept under the influence of chloroform and morphine

Urinary Concrements —Calculus in the human bladder, excepting those of phosphatic salts, is of rare occurrence in the city of New Orleans, as far at least as the stone's origin is concerned The printed reports of our Charity Hospital of ten years from 1871 to 1881, with over 55,000 patients, do not mention more than five cases of "stone in the bladder," two among the whites, three among the colored people (Though I am constrained to say, that great reliance cannot be placed upon these hospital reports, which at that period, at least, had been made up in a very loose and unsatisfactory manner for proper statistics)

---

[1] It is known that phlebitis and pyæmia have often followed neglected or badly treated cases of chronic cystitis There has lately (1881) arrived in this country from France a certain Dr Declat, who in some enthusiastic manner, proclaimed his ability to cure pyæmia with his never failing preparations of carbolic acid which he applied internally and in subcutaneous injections, and in quite large doses He also claimed the priority of the aseptic treatment, calling Lister a plagiarist If this new Messias of antisepsis would exchange the role of the alchemist and make known his wonder doing compositions he would act with more propriety and becoming a professional scholar earning a greater reputation and with more "eclat" if his assertions should prove to be true, than at present where no conscientious physician or surgeon will make use of his patent medicines, in having no other guarantee but the doctor's mere assertions and his own puffing for notoriety's sake

During a practice of thirty-two years in this city, I have operated on fifteen cases of stone and have assisted in six of others All the cases happened among whites With the exception of the children to the number of five, none were natives of the soil

From the frequency of the disease in certain countries or localities, there can hardly exist a doubt that some geological elements, or conditions of the soil, have to account for the frequency of these concrements, at least so far as those are concerned which originate in the kidneys, whilst calculi originate in the bladder, the phosphatic stones may happen anywhere, their formation depending from causes and conditions unconnected with clime, soil, or food In Germany, near the river Rhenus, where a great deal of sour wine ("Maselwine") is consumed, lithiasis is almost unknown, whilst in other parts of that country stone in the bladder is a most frequent ailment It would no doubt be of great interest to solve the question to what elements the frequency of the disease has to be attributed

The chemical composition and physical character, such as size and form of the calculus are important factors, the knowledge of which will in part direct the action of the surgeon, in the selection of the method of operation for the stone's removal With regard to the nature of the calculus, which equally plays a role here, we may discriminate between two classes of calculi, *renal* and *vesical* In one class, the calculus may cause a disease of the bladder, in the other the disease may produce the calculus, in one the disease ceases with the stone's removal, whilst in the other the disease remains and affords a separate treatment Among the compositions of the different calculi we have *uric* and *oxalic acids*, and its salts, besides *phosphates* The latter are most frequently met with in concrements which have their origin in the bladder, or form to a great extent the outer shell of renal concrements

Dr R Ultzmann, of Vienna, Austria, classifies the urinary concrements in two groups In the first he counts the *urates*, *earthy phosphates* and the *cystin* stones, which if free and not enclosed in diverticles present a type of three diameters In the second class he enrolls the *oxalates* with a type of two diameters The author views these concrements as a crystallization en masse, asserting that these diverse elementary bodies, even in such a mass crystallization, preserve their characteristics, according to which *uric acid*, *cystin*, and the *phosphates* present the three axes, belonging to the *rhombic system*, while the *oxalate of lime* belongs to the *quadratic system* (The concrements so very rare as the xanthin, indigo and urostealith he has not mentioned)

Ultzmann compares the urine with a mother liquid, out of which uric acid will be precipitated, if there is more of it in the urine than it is capable of keeping in solution, or, if too much free acid has been formed The respective concrements here have to be considered as diagnostic signs of importance But what is also, and not of minor interest and import to the practical clinicist and physiologist, is his method common to the geologist and mineralogist, of grinding the concrement to such an extra thinness that it can be examined under a reflecting light by the microscope Thus has Ultzmann originated the doctrine of the *microscopical physiography of the urinary concrements* These grounded stone segments present not agglomerations, but real mass crystallizations subordinated to the crystallographic laws, and the results obtained by the author have confirmed the correctness of his views of the origin of these concretions in the urinary tract Every crystallization inculcates the presence of a mother liquid inside of the urinary apparatus These conditions are fulfilled if the urine contains an abnormal mixture of too much acid, or alkali of too much uric acid, etc Under these conditions the concrements originate either already in the kidneys, or directly in the bladder

Detection and Recidives of Calculi —Small calculi in a full bladder are often difficult of detection, and if detected, the catching of them may be still more difficult Exceptions to these facts, as for instance of the distinguished "stone-cutter," Sir H Thompson, who, as he himself tells us, finishes the whole operation of lithotripsy, from beginning to end,—catching, crushing and evacuating the fragments,—all in the average of six minutes, are rather rare specimens of an uncommon dexterity! It affords a great *tactus eruditus* of a surgeon's fingers in exploring a bladder to detect by palpation a small calculus, and the ears, if laid under contribution, to hear the sound of striking a concrement with a bougie or catheter, have to be not less acute Quite different, besides, will it be if the calculus should be enclosed in a diverticle of the bladder In such an eventuality it may remain and grow till it finally becomes detached by its own weight One of the best pathognomonic symptoms of the presence of a calculus, if not enclosed in a diverticle, consists in the instantaneous arrest of the flow of urine in the act of being discharged, though it is not so very rare that its presence may escape the detection of both the patient and the surgeon

In detecting a calculus with the help of the endoscope and the electric light, I have no experience, and I believe that a calculus in no other way discernible, can hardly cause sufficient trouble to require such a fashionable contrivance

Recidiva of Calculi may happen after any operation for stone, be it cystotomy, lithotripsy or urethrolithotripsy, though it may be difficult to say after which method it has happened more frequently Thus Lisfranc has repeated the operation of cystotomy twelve times on the same patient, Civiale seven times, Benno Smith and Weigmann have collected

155 cases of such recidiva following most all the operations of cystotomy, sufficient proof that it is not always the fragments left behind in the operation of lithotripsy which can be accused of the reappearance of calculi after that operation. It rather seems to be a certain disposition of the system which causes these recidiva, and against which, so far, no treatment has been found to be of any avail. The frequent return of such concrements after cystotomy ought, therefore, to caution against a hasty reproach of the operation of lithotripsy on account of fragments left behind, and which, at the same time, would imply an unjust accusation of the operator. The etiological elements of such recidiva may, indeed, be manifold. Thus the concrements may be formed in the kidneys and be from there transferred to the bladder, where they continue to grow, or an alkaline condition of the urine, whereby a precipitation of insoluble phosphates "*placages phosphatiques*" may follow. They may also follow from fragments left behind in an operation, or from pieces broken off during the extraction of a calculus, or from pieces of a broken catheter or bougie, or from sharp pointed foreign bodies which have entered the bladder from some interior parts, from fragments swallowed by accident, such as pins, nails, needles, which have come into the bladder through the urethra, as is occasionally the case with children, also, from blood coagula, from an over distension of the bladder with urine, from paralysis, hypertrophy of the prostate, or strictures of the urethra, etc. All these manifold factors may, at one time or another, be the cause of the formation of a calculus, with a foreign body as the nucleus. Vesico vaginal fistulas have also been mentioned among the causes of stone. One such case came under my own observation, where a fistula and stone existed together, but here it became more probable that the stone was rather the cause of the fistula, and not the fistula the cause of the stone, and its nucleus proved that it had its origin in one of the kidneys. During the delivery of the woman the presence of the stone had been overlooked, and no doubt became the cause of a partial gangrene of the bladder and vagina, causing the fistula. The nucleus consisted of uric acid and the outer parts of phosphates. The stone had the size of a large pigeon's egg.

APPENDIX

VESICAL CALCULI IN THE URINARY BLADDER OF AN HYPOSPADIAS—A SURGICAL CURIOSITY.

Above I have named different foreign bodies which occasionally might be met with in the urinary bladder of man, forming the nucleus of certain concrements, but seldom, if ever before, has a surgeon come across a case in which the nucleus of a concrement consisted of so singular an object as in the case under consideration.

The subject of this interesting narrative was a musician, about 45 years old. A congenital deformity which stamped him an hypospadias, with the urethra of the pendulous portion of the penis left open, the latter organ presented a *membrum virile cum impotentia generandi et coeundi*. That penis reminded me of an operation said still to be performed by the inhabitants of some of the islands of the South Sea, as also among the Australians and Esquimaux—people who, in regard to culture, stand probably yet at the same prehistoric footing as the so-called *neolithic period*. I say it reminded me of what these Australians call the *mica operation*, which consists in cleaving the lower wall of the urethra for the purpose of producing sterility, and which operation they perform with a stone knife, a piece of flint they sharpen, and with which they are said to perform also laparotomy and even trepanning.

The morphological interest in our musician's case was heightened by the fact that with the urethra left open to the root of the penis from the first period of fœtal life, that membrane had grown to an extraordinary large size and length, measuring in its relaxed condition 14.5 centimetres (near 6″) in length. The opening at the root of the penis was not larger than 8 mm. in diameter, and that opening, which corresponded with the locality of the caput gallinaginis, proved the man's misfortune. Through that opening our musician had been in the habit of playing with the cork of a wine bottle, "*pour saulager la nature*," est modus in rebus, and as none are so daring as those who have long been accustomed to place their dependence on their own exertion—it being the distinct mark of genius, that it lights its own fire—our prestidigitator one day in thus pursuing the even tenor of the way of his Anacreontic desires, in playing a fortissime experienced on himself the truth that "what is considered happiness to-day may get misery to-morrow," and, like the pitcher that goes constantly to the well, is likely to break at last, so the cork, escaping once his fingers, vanished between wind and water to that bourne whence no traveller ever returns, except it be by the hand of the sympathizing surgeon.

It is properly said that "a rolling stone gathers no moss," but a rolling cork in a vesica urinaria may gather phosphates and become an annoying peregrinarian calculus. Hugging the delusive phantom of hope to play himself the successful accoucheur, our musician had at various times tried, by introducing wires, tape, fiddle strings, etc., to get hold once more of the fugitive stopper, but frustraneously. He finally discovered how truly Rabelais had said, that "the attempt to run a wind-mill by the wind squeezed out of a dead ass, be a futile enterprise of an impracticable genius," and he came to the conclusion that a good musician might turn out a very poor surgeon. He felt some embarrassment to acknowledge his foolishness. But as the man who tells one lie will have to tell a dozen more to sustain the first, he was soon caught in his own net, and forced to make a full confession.

The operation was decided upon. When the patient was under the full influence of chloroform, I succeeded, in an easy manner in extracting, with a calculus spoon, entered through the natural opening, the incrustated cork. But, from its size, no doubt could exist that another and even a larger piece was still behind. Entering the instrument again, that piece was soon grasped and brought to the entrance of the opening But it was impossible to extract it in that manner, a forceps and the percuteur were both tried, but with no better result The cork could not be compressed nor crushed, therefore the opening was enlarged with the long knife of Vacca Berlinghieri, the incision being made towards the neck of the bladder, when, with a forceps, the other piece came away quite easily Both pieces were thickly incrustated No doubt, by his efforts to get the cork out the musician, in using the wire, had cut the soft cork in two The operation was not followed by any untoward symptom, after the bladder had been well irrigated and washed out The patient was not even confined to bed for a single day Who was happier than our fiddler, when once more he held his dear and unlucky cork in his hands? A proposition of doing away with the tempting opening in restoring a normal channel he nevertheless refused I never saw him again

---

BRIEF NOTES OF THREE CASES IN WHICH PREMATURE LABOR WAS INDUCED

BY AUGUSTUS P CLARKE, M D , CAMBRIDGE, MASS

Read before the Cambridge Society for Medical Improvement Dec 22, 1884

In one case where the woman was seven months pregnant, and where premature labor was urgently demanded, I used a carbolized sponge tent This was left in for twenty four hours, when it was removed and a second one for the same length of time was introduced I also used a third tent, well carbolized After the removal of each tent I disinfected the parts with a 2 per cent solution of carbolic acid After the use of the third tent, labor pains began at irregular intervals, and were assisted by digital dilatation of the os uteri On the fourth day the fœtus (male) weighing six pounds, was expelled alive, and it survived, and the mother, though suffering from some symptoms of septicæmia, recovered, but was unable to nurse her child, owing to the want of a sufficient quantity of milk This lady had been married some ten years previously The first time I met her was when I was called to assist Dr Chas H Allen, formerly of this city, in her delivery The doctor had been with her for the most part during thirty-six hours, and although the os uteri was well dilated, and the long forceps could be applied, yet we found it quite impossible to extract the child without resorting to the operation of perforating the head, and even after this was done, we had great difficulty in bringing down the shoulders After the placenta was removed, we found that the conjugate diameter of the pelvis was hardly 2½ inches There was a marked distortion of the right ramus, thus lessening the iliac diameter, besides, the tuberosities of the ischia more closely approached each other than in a normal case At that time, 1869, we were both satisfied that our patient was unable to bear a living child at full term, and the matter of the induction of premature labor in a subsequent pregnancy was considered Some three years later I was again called to this patient, who was again in labor for the second time The os was dilating and the pains were frequent and strong, but no descent into the pelvic cavity took place I succeeded at last in accomplishing her delivery, but the child had to be sacrificed as before In June, 1874, I was again consulted by this lady, who was about five months pregnant The patient was otherwise in good health Ballottement could be distinctly felt I then advised my patient not to allow her pregnancy to continue to full term, but to submit to the chances of a premature labor induced at seven months Accordingly, on August 15 (1874) following, she submitted to an operation resulting as above detailed Soon after this her husband died, and my patient escaped further dangers of a married life

The next case to which I was called was that of Mrs. E , a Scottish lady aged twenty eight years She was delivered at the age of twenty four years of a stillborn child, before she emigrated to this country She said her labor was a tedious one, and was terminated with instruments and by the inhalation of chloroform. After coming to this country, while in New York city, she miscarried twice Her uterus was sharply anteflexed, and she suffered more or less from dysuria This was in October, 1877 September 1, 1878, I was called to attend her in labor at term The presentation was normal and of the first position The labor was unusually prolonged, owing to the narrowness of the pelvis The conjugate diameter was scarcely 2¾ inches, and the iliac diameter seemed insufficient for the exit of a living child at full term There was a contraction at the outlet of the pelvis Forceps were applied, but the child was stillborn The patient made a rapid recovery Eight months afterwards she became pregnant, May 1, 1879 I advised her as in the case of the other patient, not to allow the pregnancy to continue longer than seven months Dec 1, 1879, I inserted a sponge tent into the os uteri, this was followed by a chill and afterwards a good deal of constitutional disturbance The tent was removed after the lapse of twenty-four hours, and I waited until the third day, when I applied another carbolized sponge tent This brought on the same constitutional disturbance, but on the fourth day some fugitive pains occurred, and I resorted at intervals to digital dilatation The fœtus was born on the evening of the fifth day, but it was feeble, and it died on the third day after its birth The mother suffered a good deal from what appeared to be septicæmia, evidently superinduced by the application of the sponge tents The patient finally recovered

In another case of narrow or contracted pelvis, where the conjugate diameter did not exceed 2¾ inches, and in which I determined to induce premature labor, at about seven and a half months, I used a medium sized (No 14, French scale) olive tip bougie, introduced carefully while the patient was in Sims's position The bougie was introduced without rupturing the membranes, and passed across the fundus of the uterus in a spiral or curved direction, and then left for twelve hours, when labor supervened The labor was completed in six hours, and the infant was alive and did well. The mother made a good recovery. This case occurred in October, 1880. The mother was aged twenty seven years, and had been married six years. She was delivered of a child (female) stillborn, at Boston Highlands, Oct. 27, 1876, and another, stillborn, at Worcester, Mass., some two years afterwards. It was from her husband and from her physician, the late Dr. Henry Clarke, of Worcester, that I learned the circumstances of her delivery.

The plan of inducing premature labor by the introduction of a flexible gum elastic bougie, reported in the *Retrospect*, No. 71, p. 190 (by John C. Lucas, Esq.), is evidently a safe and easy method. My experience in the use of sponge tents, even when thoroughly carbolized, for dilating the cervix for any purpose whatever, is unsafe and often leads to irreparable mischief. For a long time I have abandoned their use altogether. The use of a flexible gum elastic bougie is more scientific. The bougie is cleanly, its presence in the uterine cavity, across the fundus, after a few hours, will often excite healthy and normal uterine contractions. And in any case where any unpleasant or any constitutional disturbances arise from its presence, it can be readily removed by the attendant, or the patient herself, before alarming or serious symptoms supervene. The bougie is also applicable in cases in which it is desirable to induce abortion for the relief of obstinate vomiting of pregnancy, that sometimes threatens the life of the patient. I have used it for such a purpose, and have found it a most valuable means of emptying the uterus of its contents. Digital dilatation, when carefully and judiciously practiced, is also a most valuable means in any case where the emptying of the uterus is urgently and speedily demanded.

An important consideration in a case where the induction of premature labor is required, is to ascertain when the time has arrived beyond which pregnancy should not continue. This can only be decided by a careful consideration of the whole history of the case. From my experience in the above cases, as well as from my general obstetric practice, I would state that in no case should the induction of premature labor be undertaken until after a most thorough study or knowledge has been gained of a previous pregnancy or pregnancies, for it is absolutely impossible to obtain any definite and reliable knowledge relative to the dimensions of the pelvis until after labor is well advanced or immediately after it has been completed.

MEDICAL PROGRESS

ANATOMY AND PHYSIOLOGY.

CONGENITAL ABSENCE OF THE LEFT LUNG.—Dr. E. Theremin (*Rev. Mensuelle des Maladies de L'Enfance*) gives two cases of this occurrence, which is so rare that it has never been determined in the living subject, and out of thirty thousand autopsies made in the past twenty five years at the Maison des Enfants-Trouvés, at St. Petersburg, only these two cases were noted. The first case lived for eleven days, and died after symptoms of fever, accelerated respiration, dullness on percussion, bronchial souffle, and disseminated sub-crepitant râles. The body appeared normal in structure and conformation, except a rudimentary development of the eyeballs. The autopsy showed intense hyperæmia of the brain, hyperæmia and nearly complete hepatization of the right lung, hyperæmia of the liver and spleen. The second case lived from February 9 to May 17, over three months. Cyanosis was present from the first, but became in time very little marked and not constant. The heart was considered as normal; a slight cough called for an examination of the chest, when mucous râles were heard over the right and *left lungs*—nearly complete dullness on percussion over the left lung—later on in life fever set in, with signs of pneumonia of the right lung, marked cyanosis and death. Nothing abnormal was found in the autopsy as regards the other organs and tissues of the body, in structure or conformation, except what will be referred to.

In comparing these two cases great similarity is seen in the anatomical disposition of the lung, of the heart, and of the circulation of the blood. In both cases there was a little cartilaginous enlargement in the position of the left bronchus, one single pulmonary artery, and one single pulmonary vein, which communicated with the vena azygos, and thence with the vena cava superioris. In neither case did the left auricle receive any pulmonary vein; the foramen ovale and the canal of Botal were narrowed or obliterated. The unique right lung, greatly developed and incompletely divided into lobes in the second case, gave an arterial blood, which, mixed with the venous blood, produced a constant cyanosis. The large caliber of the venæ cavæ and pulmonary artery, and the hypertrophy of the right auricle and ventricle, contributed to the increase of the intensity of the general cyanosis. Both children were small, and badly nourished from their birth.

The notes taken during the life of these children, by two different physicians, show that the vesicular respiration also extended to the left in the posterior portion of the thorax, and prove that respiratory murmurs of one side may extend to the opposite side, in cases where the propagation is favorable.

MATERIA MEDICA AND THERAPEUTICS.

ON THE RARER ACCIDENTAL EFFECTS OF SALICYLATE OF SODIUM.—Under this title Dr. J. Dreschfeld gives, in the *Medical Chronicle*, the details of a case of a female patient, æt. 18, suffering from nephritis, after an attack of diphtheria. For five days of her treatment for this affection, she was given salicylate of sodium, ten grains three times daily. On the third day the temperature suddenly rose from 97.9° (axilla) to 103°, pulse from 75 to 120; there was severe headache, drowsiness, dry and brown tongue, nausea and vomiting On the fourth day the patient was worse, with pain in the left lumbar region, and enlarged spleen, on the fifth day vomiting had become incessant, great dyspnœa, temperature 103 8°, pulse 130, thready The salicylate was now stopped and 15 grains of quinine given, and in a few hours the temperature became normal, and the bad symptoms abated Three days later the salicylate was renewed in doses of 10 grains every four hours, in twenty four hours' time the temperature had again risen to 103 4°, with headache and drowsiness, increase of splenic dullness, but no vomiting, and a marked erythematous rash appeared on the face, chest and arms, with some swelling of the face The drug was stopped, and these peculiar symptoms disappeared in a few hours Again some days later, an erythematous rash appeared all over the body, the face, arms, and legs being very œdematous, the lips also much swollen, the temperature rising to 101°, pulse 100, respiration 28 The urine being tested with perchloride of iron, a distinct salicylic acid reaction was obtained These symptoms also subsided in a few days, and it was assumed that the night nurse had given a dose of salicylate by mistake A week later, in order to confirm this suspicion, 5 grains of the salicylate were given at two P M The patient's temperature was then normal, the tongue was clean, pulse 72, respiration 18 At three P M (one hour later) the patient had a rigor, temperature 100 2°, pulse 120, respiration 39, with great dyspnœa and oppression The patient was drowsy, her face dusky, and her lips bluish At 6 30 P M, temperature 101 4°, respiration 36 A marked erythematous rash was seen on the face, back of arms and forearms On the following day patient feels again much better The temperature is normal, pulse 75, respiration 18, the rash is disappearing

There can be no doubt, then, that the symptoms above detailed were due to the salicylate of sodium (more than twenty patients in the hospital were taking the drug at the time, from the same stock) It is curious to notice that the idiosyncracy against the drug increased with each successive administration, for whilst, during the first administration, the symptoms only came on on the third day, in the last we found the patient's temperature had already risen three degrees an hour after the administration of 5 grains Again, it will be noticed that the symptoms were not always the same—the rash was scarcely perceptible during the first attack, the sickness was absent during the third attack, the dyspnœa chiefly marked during the first and last attack, whilst a rigor appeared in the second and fourth attack Immediately after each attack the patient passed some urine, which contained some urea

In his comments on his case Dr Dreschfeld finds four cases in medical literature where the pyrexia was well marked, but only in one of them does he find erythema to be present That we have to do with vaso-motor phenomena is evident from the erythema, the œdema, and the profuse sweating Experiments on animals have clearly shown that salicylic acid and its allies act on the vaso motor centre A rise of temperature has also been noticed in experiments on animals Skin eruptions without pyrexia seem to occur more frequently as an accidental effect of salicylate of sodium He cites a case of articular rheumatism, where fifteen grain doses, three times daily, soon produced well-marked urticaria, on discontinuing the drug the urticaria disappeared, but reappeared upon its resumption, although it was much less troublesome A lady after using a vaginal injection containing salicylic acid, was affected with erythema nodosum, which persisted for more than four days, and affected also the lips and mucous membrane of the mouth The lady herself at once ascribed the effect to the drug, as on a previous occasion, the use of salicylate of sodium for rheumatic pains had produced in her exactly the same symptoms This leads him to infer that the complication of erythema nodosum with acute rheumatism, may in many cases be due to this drug The dyspnœa may form the most prominent feature, and may even lead to a fatal issue He notes two cases where he has observed it—once in phthisis and once in rheumatic arthritis The dyspnœa resembles very much that seen in diabetic coma The number of respirations is not increased, and may even be diminished, but there is an excessive craving for air, the pulse becomes small, and frequently the temperature shows no alteration Experiments on animals show that the influence of salicylate of sodium on respiration is very similar Small doses increase the respiration, large doses produce marked dyspnœa, often with diminished respiratory frequency, and eventually death seems to be caused by paralysis of the respiratory centre

ON ABSINTHINE —Dr Fernand Roux (*Bulletin Gen de Therep*) has found that the common or great absinthe, artemisia absinthium, contains in its bitter principle, absinthine, certain properties that are not toxic and that are of therapeutic value To determine its degree of toxic effect he gave the drug in small doses for a long continuous period of time, and then in large doses, experimenting upon chickens, coming to the following conclusions 1st, Absinthine is not toxic in its effects even in a strong dose (2 grammes in a chicken) This result disagrees with the opinion of most authors 2nd, Its prolonged use in small doses does not give any disagreeable symptoms, 3rd, It seems to have a favorable effect upon the bowels without inducing diarrhœa, when given in moderate doses

To illustrate its therapeutic effect, Dr Roux gives the details of seven cases, which lead him to the opinions

1st Absinthine as obtained by the process of Duquesnel, the bitter principle of absinthe is not toxic

2nd Absinthine is a drug which is useful in chloro-anæmia, convalescence from serious diseases which have weakened the digestive organs, and anorexia without organic lesion of the alimentary canal

3rd Absinthine is especially indicated when there exists with anorexia an obstinate constipation

4th The most convenient dose is 10 centigrammes, ten minutes before eating, twice daily

MEDICINE.

ACUTE RHEUMATIC ARTERITIS.—A case which possessed considerable interest and not a little rarity, was narrated by M. Legnux at a recent meeting of the *Sociète Medicale des Hopitaux* (*Lancet*). The patient was a young lady, aged twenty two, whose family history was only characterized by the presence of the arthritic diathesis. In July, 1884, she had a second attack of acute rheumatism, a first having occurred at the age of twelve years, but had left no trace behind it. The rheumatism was of a sub acute character, some joints became painful, rose colored, and a little swollen, but during the moderate fever an eruption of nodose erythema appeared on the front surface of both legs. After the lapse of three weeks the patient went to the seaside, and seemed to improve considerably. At the beginning of August there was quotidian fever, which could only be explained on the assumption of a malarial origin. On the 15th of August there suddenly appeared numbness of the left hand, forearm and arm, soon followed by acute pains and inability to move the fingers or other parts of the limb. When seen by a doctor after these new symptoms, the radial, ulnar and brachial pulse could not be felt on the left side, the limb was icy cold, the hand and forearm were a little swollen, and presented on their dorsal aspect some spots of a rose brown color. Gangrene was feared, but did not occur. The fever, although somewhat abated by the administration of sulphate of quinine, still continued, and after the fresh incident increased once more, the pulse numbered 110 to 120 a minute, the temperature reached 38° to 39° c., and soon præcordial pain, dyspnœa, palpitation, and a murmur of systolic time marked a pre-existing hæmic bruit. The murmur was loudest at the apex beat, but extended towards the base and all over the aortic area. The first diagnosis made by the patient's ordinary attendant was ulcerative endocarditis with embolic thrombosis of the left brachial artery. There was a little tenderness about the left brachial artery. Dr. Charles Hardy, who saw the patient later, suggested that acute rheumatic inflammation of the artery existed because of the nodosities to be felt along the vessel, of the sensitiveness of the vessel, and of the presence of a bruit all along the thoracic aorta. The obliteration would on this opinion have been due to the acute arteritis, possibly starting from the endocardium and aorta. The limb was kept absolutely at rest, the pains were calmed by hypodermic injections of morphia, and small doses of iodide of potassium were administered. Some time after M. Legnux saw the patient for the first time. The cardiac disturbance was then marked by loud bruits, and the action of the heart was so tumultuous that it was almost impossible to differentiate the various factors of this commotion. There was an intense bruit all down the vertebral column, corresponding to the path of the aorta, auscultation over the left subclavian region yielded a loud bruit. There was a tender pulsatile dilatation of the axillary artery, of the size of a large plum. Below the aneurism the brachial artery was to be felt as a hard, fibrous, pulseless cord. The limb was pale, flabby, wasted and motionless, the hand was atrophied, and a deep furrow in front of the lunula of the nails indicated the period at which circulation had been almost completely arrested. A small degree of sensibilty remained. A slight effusion into the right pleural cavity was diagnosed. The ultimate issue of the case is not yet known.

AUTOPHONY.—Prof. Berthold, of Kœnigsburg (*Revue Mensuelle de Laryngologie, Journal des Sciences Medicatise de Lille*), describes autophony as the pathological resonance of the voice of the subject himself, as well as of the respiratory sounds and arterial pulse. It is most frequently caused by a nasal or pharyngeal catarrh of long standing, a catarrh producing an abnormal dilatation of the Eustachian tube, by atrophy of its mucous lining. A contraction of the muscles of the tube, and the retraction of the pharyngeal opening following an ulcer, may also produce the dilatation and consequent autophony.

The symptoms consist of an exaggerated resonance of the voice of the subject himself, and of the sounds of respiration, to which are added many times the sounds of the pulsation of the vessels. As the autophony is often associated with an exacerbation of a chronic naso-pharyngeal catarrh, and to an acute inflammation of the tympanum, the symptoms of these affections are added to the exaggerated resonance.

As symptoms pertaining to autophony, there should be mentioned the painful sensation to the subject which accompanies speaking, coughing or sneezing, as well as the perception of external noises. To these must be added the sensations felt by the patient during inspiration and expiration, while the mouth is closed, as caused by a movement of the tympanum towards the interior during inspiration, and towards the exterior during expiration, a movement which is readily made visible. With these the patient has a sensation of pressure and fullness in the external auditory canal.

If the phenomena of resonance be very marked, they complain also of a crackling noise like the brisk separation of mucous walls. With this is associated a sense or drawing upon the tympanum. External noises seem to be reinforced. The noises of a passing carriage in the street are very painful to the patient. Rubbing the concha of the ear between the fingers is much more readily appreciated than on the sound side.

Prognosis is always favorable, when there is no complication, and when there exists neither atrophy of the mucous membrane of the tube, nor cicatricial formation at its pharyngeal opening. In the majority of cases, after the catarrh, the mucous membrane is eventually completely relieved. Habit, moreover, enables the patient to support the symptoms readily, when once the pain has disappeared.

Treatment is the same as with chronic nasal, pharyngeal and tubal catarrh. Frequent nasal douches of warm salt water and steam are beneficial. Brenner recommends the insufflation through the tube of sulphate of zinc ¼ to ½ p. 100.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 65 RANDOLPH STREET,
CHICAGO ILLINOIS

SATURDAY, JANUARY 24, 1885

ARRANGEMENTS FOR THE NEXT MEETING OF THE AMERICAN MEDICAL ASSOCIATION —We have assurances that the Committee of Arrangements at New Orleans, of which Dr Samuel D Logan is Chairman, is actively at work making all the necessary preliminary preparations for a large and profitable meeting of the Association in that city, commencing on the last Tuesday in April next The officers of the several Sections are, or should be, actively engaged in securing the preparation of papers and reports for their respective Sections, and are anxious to be furnished as early as possible with the titles of all papers intended by their authors to be presented at the next meeting, that they may be properly placed on the general programme to be prepared and printed by the Committee of Arrangements before the meeting To aid them, and facilitate the correspondence of members, we reproduce the names and postoffice address of the officers of the Association, and of each of the Sections as follows

President of the Association, Dr H F Campbell, of Augusta, Georgia, Permanent Secretary, Dr Wm B Atkinson, 1400 Pine street, Philadelphia, Pa, Assistant Secretary, Dr W H Watkins, of New Orleans, La, Treasurer, Dr Richard J Dunglison, Lock Box 1274, Philadelphia, Pa, Librarian, Dr C H A Kleinschmidt, of Washington, D C, Chairman of the Committee of Arrangements, Dr Samuel D Logan, of New Orleans, Louisiana

Section of Practical Medicine and Materia Medica Chairman, Dr H D Didama, Syracuse, New York, Secretary, Dr G M Garland, Boston, Mass

Section of Surgery and Anatomy Chairman, Dr Duncan Eve, Nashville, Tenn, Secretary, Dr T B King, Allegheny, Pennsylvania

Section of Obstetrics and Diseases of Women Chairman, Dr R S Sutton, Pittsburgh, Penn, Secretary, Dr R T Jelks, Hot Springs, Ark

Section of Ophthalmology, Otology and Laryngology Chairman, Dr J A White, Richmond, Va, Secretary, Dr Eugene Smith, Detroit, Mich

Section of State Medicine Chairman, Dr E W Schaufler, Kansas City, Mo, Secretary, Dr J N McCormick, Bowling Green, Ky

Section of Diseases of Children Chairman, Dr J H Pope, Marshall, Texas, Secretary, Dr S S Adams, Washington, D C

Section of Oral and Dental Surgery Chairman, Dr W W Allport, Chicago, Ill, Secretary, Dr E C Briggs, Boston, Massachusetts

Committee on Necrology Chairman, Dr J M Toner, Washington, D C

It will add much, both to the pleasure and profit of all who attend the meeting, if the by laws requiring all parties intending to present reports or papers, to notify either the Chairman of the Committee of Arrangements, or the Chairman of the Section in which the paper would belong, at least thirty days before the time of the annual meeting, and that all papers be complete in their preparation, and when presented or read they be passed directly into the hands of the Secretary of the Section or of the Association, could be literally complied with And it takes no more of the time of any member to complete a paper in good order before the time of meeting, than it does to present an imperfect abstract, not of his paper, but of what he intends his paper to be some months hence, when he vainly expects to have more time to write it out There has been too much of this imperfect work in the past, too many papers read by abstract or title and referred for publication, that had no existence at the time, and occasionally one that never gained a visible existence afterward Every member should take pride in doing his work promptly, and doing it well

PERMANENT MEMBERSHIP BY APPLICATION —We stated fully, soon after the last meeting of the American Medical Association in Washington, that the constitution of that organization had been so amended that permanent membership could be obtained without actually attending an annual meeting Any member of a regular State, District, or County Medical Society entitled to send delegates to the National Association, can become a member of the latter organization by simply sending to the Treasurer, Richard J Dunglison, M D, lock box 1274, Philadelphia, Pa, *five dollars* as annual membership fee, accompanied by a certificate signed by the President and Secretary of the State or local Society to which he belongs, stating that he is a member in good standing, and desires to be enrolled as permanent member of the National Association The payment of the five dollars to the Treasurer also entitles him to the JOURNAL of the Association for the current year, during which he becomes enrolled as a member And he will continue his membership and the reception of the JOURNAL, so long as he pays to the Treasurer his annual membership fee, and remains in good standing in the State or local Society in the place of his residence A considerable number of those who took the JOURNAL the first year as subscribers, have made application, as above stated, and are now enrolled and receiving it as regular members of the Association It is desirable that all should do so, who can furnish the required certificate of good standing in the State or local Society where they live

CONGRESS AND PUBLIC HEALTH —Several weeks since we published in the JOURNAL the copy of a bill to establish a National Board of Health, as prepared by the Conference of State Boards of Health, and submitted to Congress soon after that body assembled in December In this issue of the JOURNAL, under the head of State Medicine, we give the full text of a bill for the establishment of a Bureau of Health as a permanent department of the National government The bill has been prepared by Dr O W Wight, of Detroit, Mich , who has devoted much time and attention to sanitary matters and sanitary legislation, and its merits deserve careful consideration

It was introduced into the Senate by Senator Palmer on the 9th inst While it is not probable that the present Congress will do more than to appropriate an extra sum of money to be placed at the disposal of the President for use in case a cholera epidemic should appear, the subject of a permanent National Department of Health is one of much importance Whether it shall take the form of a National Board of Health, or of a Bureau of the Government, is a question which should be fully considered by the medical profession, and for the temperate and intelligent discussion of which our columns are open

BURNING OF THE EASTERN ILLINOIS HOSPITAL FOR THE INSANE —One of the buildings constituting this asylum at Kankakee, Illinois, was burned on the morning of the 18th inst , causing the immediate death of seventeen of the inmates The cause of the fire is stated to have been the too close proximity of pine timbers to one of the furnaces, while there had been no adequate means provided for extinguishing a fire after it had commenced

SOCIETY PROCEEDINGS

CHICAGO GYNÆCOLOGICAL SOCIETY.

Regular meeting, Chicago Gynæcological Society, Dec 19, 1884 The President, Dr H P Merriman, in the chair

Dr W H Byford read a paper entitled, "A Case of Mural Pregnancy " The history of the case was obscure The patient, 28 years old, married seven years, had one child, six years old She supposed she became pregnant, for the second time, in February, 1883 In April she became fatigued, and had hæmorrhages which continued until May 9,—about four weeks Oct 14th, a discharge of yellow fluid, about one gallon in quantity, occurred A putrescent, sero sanguineous discharge followed, continuing three months January, 1884, a large brownish mass, with very fœtid odor, was expelled After this event, menstruation occurred until July In May, she was quite large, and had bearing-down pains She entered the hospital Oct 6, 1884 She was tapped Oct 18, and about four quarts of thick, tenacious fluid, resembling the fluid of an ovarian cyst, was removed This fluid coagulated on the addition of nitric acid and on boiling Assisted by Dr. R Tilley, a microscopical examination was made, with negative results The ' Drysdale " cell was not found Laparotomy was performed, and a fœtus with placenta was removed without hæmorrhage or difficulty In order to secure perfect drainage, it was considered best to remove the uterus The operation was performed on Oct 30, the patient did not react, but died within twenty-four hours. Prior to the operation, the patient was extremely reduced by her protracted sufferings Dr Byford, in a similar case, at the present time, would elect the vaginal operation The specimens removed from the woman were exhibited as supporting the diagnosis of mural pregnancy

This was the second case of mural pregnancy that had come under the reader's observation within a period of five years The first case was reported to the CHICAGO GYNÆCOLOGICAL SOCIETY, some time ago The patient was in labor and moribund when Dr Byford saw her She had been in labor until exhausted There was no difficulty in making a diagnosis The head was low down in the pelvis, almost on the perineum The *os uteri* was well-nigh inaccessible behind and above the symphysis The body of the uterus, somewhat enlarged, could be felt in the lower and anterior part of the abdomen, attached to the tumor containing the fœtus The fœtus could be felt through the abdominal walls, surrounded by a thick involucrum, apparently as thick as the uterine walls Fœtal extremities could be distinguished When dissected, the sac in which the fœtus was contained, was found to consist of a thick layer of muscular fibres These fibres were directly continuous with those of the uterus The tubes and ovaries lay on either side of the lower portion of the sac The fecundated ovum had made its way down the tube, become lodged in a diverticulum in the uterine wall, and was gradually extruded into the cavity of the abdomen The fœtus was thus developed within the uterus, though not within the uterine cavity The resemblance to normal pregnancy is great in the presentation and position of the fœtus, deep down in the pelvic cavity, behind the vagina The head, in this case, was fixed by the concentric contraction of the uterine fibres by which it was surrounded, and could be easily outlined as it lay there covered by the posterior vaginal wall

The specimen presented is much less perfect than the one described, because of the numerous effects wrought upon it during the great length of time it remained in the maternal body, and the mutilation consequent upon enucleation

The treatment of these cases ought to be considered apart from that of extra uterine pregnancy at term It is always a matter for special consideration, in connection with each case as it presents itself, whether or no the removal of the fœtus at term, in extra uterine gestation, should be attempted The dangers of laparotomy are greatly increased by the inability to remove the placenta The surface to which it is attached has no contractile power, so that the divided vessels are left patulous If hæmorrhage does not immediately prove fatal, the blood is a source of sepsis that must almost certainly destroy the patient Laparotomy would more likely prove successful, if performed some days after the birth of the child In these cases of ectopic or interstitial uterine pregnancy, the fœtus may be easily removed through the vagina An incision made through the posterior vaginal wall would completely uncover the presenting part, and enable one to apply the forceps or attack it with the perforator and crotchet, as in ordinary labor After the removal of the fœtus, the placenta should be allowed to separate spontaneously

Since writing this report, Dr Byford has seen a case reported in the *Annales de Gynæcologie*, July 1884, occurring in the practice of Mr Matheson, of England, illustrative of the execution of this plan The case was reported to the London Obstetrical Society under the title, "Extra-Uterine Pregnancy, the Extraction of a Living Fœtus Through the Vagina" The child was slightly asphyxiated, but survived A sponge saturated with perchloride of iron was introduced into the sac, after removal of the placenta The mother recovered It would seem that the author did not suspect his case to be one of interstitial pregnancy During the discussion that followed, only one of those present expressed the opinion that it was of that variety Mr Griffith thought it was either interstitial pregnancy, or one in which the fœtus was developed in one portion of a double uterus

DISCUSSION

Dr Edward Warren Sawyer thought that interstitial pregnancy meant the development of the ovum in the uterine portion of one of the tubes In Dr Byford's case the uterine portions of the tubes were not involved It reminded him of a case he had seen near Denver In this case a secondary uterus, with muscular walls, had been developed, but as the tubes were not involved he did not feel justified in designating the case one of interstitial pregnancy

Dr D T Nelson said, with reference to the treatment of the placenta, that Dr Byford's advice was that usually recommended in the text-books The placenta should be left alone in those cases in which the walls of the secondary uterus were not muscular He had seen a case in the museum of the Chicago Medical College, in which no muscular fibre could be detected in the walls When the walls of the adventitious uterus were muscular, it was questionable whether or no the placenta should be left alone If the placenta is removed, there is danger of hæmorrhage, if the placenta remains, there is danger of sepsis When there was reason to suppose that contractions of the adventitious uterus would check hæmorrhage, he thought the placenta should be removed He had no experience in these cases

Dr E C Dudley replied to Dr Nelson Women, in cases of extra-uterine pregnancy, in which the placenta has been allowed to remain, do not die of sepsis He had seen two or three cases in which the sac had been united to the abdominal incision Whenever evidence of sepsis occurred, the sac was washed out, and the temperature immediately fell to the normal The placenta, under these circumstances, is spontaneously eliminated in about three weeks

It required phenomenal powers of diagnosis to tell, in the concrete case, whether or no the sac had sufficient muscular fibres to prevent hæmorrhage The placenta should be permitted to remain within the sac

Dr J H Etheridge thought that if, on microscopical examination, it was found that the muscular fibres of the normal uterus were continuous with those of the adventitious uterus, the case was one of mural pregnancy In cases of abdominal pregnancy, there was a line of demarkation between the normal and adventitious uterus

Dr A Reeves Jackson thought the members of the society were greatly indebted to Professor Byford for the presentation of such an interesting specimen He thought, however, with Dr Sawyer, that the results of the anatomical investigation did not support the author's diagnosis The uterine portions of the tubes were not involved So valuable a specimen deserved very close microscopical and macroscopical examination It ought to be referred to a competent pathological anatomist

Dr John Bartlett thought the ovum had not passed through the tube, but had been developed in the broad ligament, beneath the peritoneum, and had, in this manner, derived muscular fibres from the uterus

Dr W W Jaggard referred to the fact that, next to ovarian pregnancy, interstitial pregnancy was of most infrequent occurrence Up to the present time, about thirty cases, in regard to which the diagnosis was positive, had been reported Interstitial or mural pregnancy included other sites of development than the uterine portions of the tubes Dr Gilbert's case, reported in the *Boston Medical and Surgical Journal*, 3d March, 1877, and alluded to by Professor Lusk in his "*Treatise on Midwifery*," was a case in point The ovum in this case was developed in what seemed to be a bifurcation of the Fallopian tube In Dr Byford's case, the tubo-uterine orifices were not involved The sac was extrinsic to the uterine walls It was probably a case of abdominal pregnancy, in which the ovum became attached to the posterior uterine wall, and derived muscular fibres from this locality The fact that a continuity of muscular fibres from the normal uterus to the adventitious uterus might be ascertained upon microscopical examination, would prove nothing as to the nature of the pregnancy Dr Byford's case resembled that of Janvrin, in which the ovum lodged on the posterior uterine wall and developed in this situation, involving the posterior wall in its sac The specimen was worthy of a more exact investigation, and should be placed in the hands of a competent pathological anatomist

Dr Sawyer said that abdominal pregnancy, with location of ovum on posterior uterine wall, was not at all improbable He then referred to Bischoff's and Leopold's observations and experiments with relation to the "external wandering over of the egg" Beigel had ridiculed this idea It was like a blind man introduced into a large, empty room, with a thread in his hand, seeking to find and thread the eye of a needle, located in some indefinite quarter of the room Notwithstanding this sarcasm, the fact of the external wandering over of the egg was a fact of positive knowledge The egg may pass from one ovary to the opposite Fallopian tube, through the abdominal cavity He thought the specimen exhibited was one of abdominal pregnancy

Dr Dudley thought the fact of the external wandering over of the egg was not disputed at the present time Playfair in his treatise on midwifery, gave a clear exposition of the subject

Dr Charles Warrington Earle said that the fact of external wandering over of the egg was fully recognized twelve years ago

Dr Sawyer said the ovum in abdominal pregnancy might be attached to the posterior wall of the uterus, the mesentery, under surface of the liver, or to other viscera

Dr Nelson made the remark that in both of the cases cited by Dr Byford, *deciduæ* had been cast off by the *uteri*

Dr Jackson said that Frankel was of the opinion that the formation and extrusion of a decidua was a constant occurrence in extra-uterine pregnancy It was pathognomonic of the condition

Dr W H Byford was not surprised that certain members did not agree with him in his diagnosis He thought that in the first case the fecundated ovum passed through the tube, but had found some diverticulum in the uterine cavity, and had passed into the posterior wall, had developed in this region, pushing the wall before it Some of the reasons for this position were as follows

The muscular elements of the sac were directly continuous with the uterine muscle He did not believe that such a muscular sac could develop adventitiously in pregnancy in the abdomical cavity He had seen cases of abdominal pregnancy in which he could detect no muscular fibre The head presentation, down deep in the pelvic cavity, in the direction of the resultant of the forces developed by uterine contractions, supported his view of the case

It is not necessary for the production of mural pregnancy that the tubes be involved He thought there was much in the remarks of Dr Nelson and Dr Dudley In cases in which there was sufficient contractility, it was best to remove the placenta Even under these circumstances it was not absolutely necessary There was no danger in allowing the placenta to remain

Finally, he was very positively of the belief that the two cases referred to in this paper, were examples of mural pregnancy The peritoneum was a boundary line between mural and abdominal or peritoneal pregnancies

Dr Sawyer asked the question Is the peritoneum a boundary line of importance in the macroscopical or microscopical differential diagnosis between abdominal and mural pregnancies?

Dr Jaggard, in reply, said that the peritoneum was no barrier What was the peritoneum? Dr Etheridge, in an article on "Chronic Adhesive Perimetritis," published in a recent number of the *Chicago Medical Journal and Examiner*, had ably sketched the anatomy of this membrane It was developed [illegible] of connective tissue, according to Rindfleisch, [illegible] other distinguished anatomists It offered absolutely no barrier to the attachment of the ovum to the posterior uterine wall, and its development in this situation, with the derivation of muscular element from the normal uterus

On motion, Doctors Byford, Merriman and Jaggard were appointed a committee to select a competent pathological anatomist, who did not belong to the society, to examine the specimen and report at the next regular meeting It was specified in the resolution that the *pathologist should be amply paid for the labor*

Dr Etheridge then exhibited a placenta with calcareous deposits The placenta was removed from the body of a woman pregnant for the first time, who had probably carried the fœtus 292 days The calcareous deposit was probably the result of fatty metamorphosis of the upper layers of the *decidua serotina*

Dr Sawyer said the placenta was interesting, but not uncommon It has been erroneously believed that such *placentæ* are of syphilitic origin He thought the connection with prolonged gestation was established

Dr Dudley referred to the calcareous deposit in the walls of the arteries supplying an ovarian cyst, which he had removed some years previously

Dr Jackson related the history of a case, in which he had removed a mass of calcium carbonate, situated in the recto-vaginal septum, one and one half inches from the vulvo vaginal orifice There was no fatty metamorphosis in this case

Dr Earle thought there was an unreasonable tendency to ascribe such cases to the effects of syphilis Hydatidiform, degeneration of the chorionic villi, and hydrops amnii received a similar erroneous etiology

Dr Etheridge said that the deposits were composed of the phosphate and carbonate of calcium These had an affinity for albumens and fatty acids residing in the cotyledons Similar calcareous deposits were found in the fibroids, thrombi, encysted trichinæ, and in the lithopædia of extra-uterine pregnancy

Dr W H Byford thought the connection between prolonged gestation and calcareous deposits in the placenta, was established He thought that Dr Etheridge would find, on microscopical examination, that the changes had occurred exclusively within the vessel walls

The Society then adjourned, to meet on the third Friday evening in January, at the residence of Dr E C Dudley, No 2317 Indiana avenue, at 8 o'clock

The business of next meeting will be

(1) Report of the pathologist, Dr Christian Fenger, on Dr Byford's specimens

(2) Exhibition of specimens from a double ovariotomy, by Dr E C Dudley

(3) Discussion of certain methods by which the second stage of labor may be rendered easier, by Henry T Byford

W W JAGGARD, M D , *Editor*

2330 Indiana avenue, December 22, 1884

STATE MEDICINE

A BILL TO PREVENT THE INTRODUCTION AND DIFFUSION OF CONTAGIOUS AND INFECTIOUS DISEASES IN THE UNITED STATES, AND TO PROMOTE THE GENERAL SANITARY WELFARE OF THE PEOPLE.

Be it enacted by the Senate and House of Representatives in Congress assembled, that

Section 1 There shall be, and hereby is, established in the Treasury Department a Bureau of Public Health, charged with the execution of all laws passed by Congress relating to quarantine and the public health, and with the framing and execution of sanitary regulations as hereinafter provided The chief officer of the said Bureau shall be denominated the Commissioner of Public Health, and shall be under the general supervision of the Secretary of the Treasury He shall be appointed by the President, by and with the advice and consent of the Senate, and shall hold his office for the term of five years, unless sooner removed by the President, upon reasons to be communicated by him to the Senate, and until his successor shall be appointed and confirmed

Sec 2 There shall be allowed to the Commissioner of Public Health an annual salary of four thousand five hundred dollars, payable monthly, and actual necessary traveling expenses in the performance of his official duties, for which vouchers shall be rendered

Sec 3 The Commissioner of Public Health shall, within fifteen days from the notice of his appointment, take and subscribe the oath of office, for his use the Secretary of the Treasury shall provide suitable offices, and he shall employ, from time to time, the necessary clerks, to be appointed and classified by the Secretary of the Treasury, to discharge such duties as the Commissioner of Public Health shall direct

Sec 4 The Commissioner of Public Health shall appoint, by and with the advice and consent of the Senate, seven superintendents of external and internal quarantine, embracing both infected persons and infected or adulterated goods, for the following districts, to-wit

First One for the Atlantic coast, from the port of Baltimore (exclusive), northward to the boundary line between the United States and the British Provinces, and thence along said boundary line to the intersection of the same with the river St Lawrence,

Second One for the Atlantic coast from the port of Baltimore (inclusive) southward to Key West (inclusive),

Third One for the Gulf coast from Key West (exclusive) to the Mexican border, and thence along the boundary line between the United States and Mexico to the head waters of the Rio del Norte,

Fourth One for the Pacific Coast and the States bordering thereon and the boundary lines as far eastward as the head waters of the Rio del Norte and of the Missouri river

Fifth One for the coasts of the lakes and rivers of the northern boundary of the United States and as far west as the head waters of the Missouri river

Sixth One for the inter-state travel and traffic of all States bordering on the Atlantic ocean or east of the Allegheny mountains

Seventh One for the inter-state travel and traffic of all the States in the Mississippi Valley

The tenure of office of such superintendents of quarantine shall be the same as that of the Commissioner of Public Health Their compensation shall be three thousand six hundred dollars per annum each, payable monthly, and their actual and necessary traveling expenses in the discharge of their duties, for which they shall render vouchers Like the Commissioner of Public Health, they shall take and subscribe the oath of office Their duties shall consist in executing, under the direction of the Commissioner of Public Health, the regulations provided for in the next following section, and to make full reports thereof

Sec 5 The Commissioner of Public Health, aided by the aforesaid Superintendents of quarantine, shall frame a code of regulations for the conduct of the external and internal quarantine of the United States The sole aim and scope of such regulations shall be for the protection of the people against contagious and infectious diseases and against the dangers to life and health from poisonously adulterated goods for the use of the people Such regulations shall conform, as far as practicable, to the local quarantine regulations in the several States It shall be the duty of the Bureau of Public Health to supplement and not to antagonize the efforts of State and municipal boards of health in the work of sanitation Such regulations may embrace provisions for obtaining in connection with the consular service of the United States special information concerning the shipment to this country of infected persons and of infected or poisoned goods and for the arrest of the same before landing Such regulations may also contain proper provisions for the detention and disinfecting of infected persons and goods in transit from one State to another, and for the destruction of goods infected and poisoned to such a degree that no reasonable process of purification can make the same safe Such regulations shall be approved by the Secretary of the Treasury, the Attorney General and the President, and also by the Secretary of State so far as any provisions looking to the cooperation of foreign consuls are concerned, before the same shall become of any validity, but after such approval and after official publication, they shall have the force of law, for the violation of which the proper Federal courts shall take cognizance

Sec 6 The Commissioner of public health shall appoint, by and with the advice and consent of the Senate, an Inspector of the ventilation, draining and plumbing of all buildings belonging to the United States The compensation and tenure of office of said Inspector shall be the same as that of the Supervisors of quarantine He shall also take and subscribe the oath of office The Commissioner of Public Health, aided by said Inspector, shall prepare a code of regulations for the ventilation, draining and plumbing of public buildings, which said regulations, when approved by the Secretary of the Treasury, the Attorney General and the President, and officially published, shall have the force of law, with which all public buildings hereafter constructed shall conform, and when any existing buildings are undergoing repairs, the same shall, so far as practicable, be thereto applied The duty of such Inspector shall be to execute, under his personal supervision, the aforesaid regulations, and to make full reports thereof to the Commissioner of Public Health

Sec 7 The Commissioner of Public Health shall appoint, by and with the advice and consent of the Senate, a Chief Clerk of his Bureau, who shall conduct the correspondence and keep the records thereof, and, during the absence or disability of the Commissioner of Public Health, may be designated by him, with the assent of the Secretary of the Treasury, to act as his deputy, or in case of the removal or death of the Commissioner of Public Health may be designated by the Secretary of the Treasury and the President to act as head of the Bureau till the vacancy is filled The Chief Clerk shall take and subscribe the oath of office, and his compensation and tenure of office shall be the same as that of the Superintendents of quarantine

Sec 8 The Commissioner of Public Health shall appoint, by and with the advice and consent of the Senate, a Public Analyst, who shall make or superintend chemical analyses and microscopical examinations of all substances submitted to him for such purpose by the Commissioner of Public Health, and prepare full reports of the same He shall take and subscribe the oath of office, and his compensation and tenure of office shall be the same as that of the Chief Clerk aforesaid The Public Analyst shall be provided with a proper laboratory, apparatus and instruments, for doing his work well, by the Secretary of the Treasury

Sec 9 The Commissioner of Public Health and the Surgeon General of the Army shall prepare a code of proper regulations for the better sanitation of the Army of the United States, which said regulations, when approved by the Secretary of War, the Attorney General and the President, and officially published, shall have the force of law and shall be executed by surgeons in the Army, under the supervision of their military superiors

The Commissioner of Public Health and the Surgeon General of the Navy shall prepare a code of proper regulations for the better sanitation of the Navy of the United States, which said regulations, when approved by the Secretary of the Navy, the Attorney General and the President, and officially published, shall have the force of law, and shall be executed by surgeons in the Navy, under the supervision of their naval superiors

The Commissioner of Public Health and the Commissioner of Education shall prepare a code of proper regulations for the better sanitation of all schools within jurisdiction of the United States, which said regulations when approved by the Secretary of the Interior, the Attorney General and the President, and officially published, shall have the force of law, and shall be executed by the Commissioner of Education

The Commissioner of Public Health and the Surgeon General of the Marine Hospital Service shall prepare a code of proper regulations for the better sanitation of merchant vessels sailing under the flag of the United States, which said regulations, when approved by the Secretary of the Treasury, the Attorney General and the President, and officially published, shall have the force of law, and shall be executed by the Surgeons of the Marine Hospital Service, under the supervision of the Surgeon General of said service Any vessels neglecting or refusing to comply with the aforesaid regulations shall forfeit their right of registration

The Commissioner of Public Health and the Commissioner of Agriculture shall prepare a code of proper regulations for the better sanitary transportation from State to State, of animals designed for the food of man, which said regulations, when approved by the Secretary of the Treasury, the Attorney General and the President, and officially published, shall have the force of law, and shall be executed by the agents of the Agricultural Department, under the supervision of the Commissioner thereof, or by the Superintendents of quarantine herein provided for, under the supervision of the Commissioner of Public Health

The Commissioner of Public Health and the President of the American Medical Association shall prepare a code of regulations for the practice of physic and surgery, and midwifery, in any place or territory under the jurisdiction of the United States, which said regulations, when approved by the Secretary of the Interior, the Attorney General and the President, and officially published, shall have the force of law, and shall be executed by the Commissioner of Public Health Such regulations shall not include the Army, Navy and Marine Hospital Medical Services For the service aforesaid the President of the American Medical Association is hereby appointed, and shall receive such compensation therefor as may be agreed upon between him and the Commissioner of Public Health with the approval of the Secretary of the Treasury

Sec 10 All goods designed for the food or drink of man, for wearing apparel, or for the furniture or decoration of habitations, so poisoned by adulteration, by coloring matter, or by any ingredient whatsoever, as to become demonstrably dangerous to human life or health, are hereby declared to be contraband of commerce anywhere within the exclusive jurisdiction of the United States, and may be seized, detained, confiscated or destroyed by the Commissioner of Public Health or his agents, with the approval of the Secretary of the Treasury, the Attorney General and the President

Sec 11 The Commissioner of Public Health may call on the President to detail army surgeons, with the concurrence of the Secretary of War, or navy surgeons, with the concurrence of the Secretary of the Navy, to investigate special diseases or their causes When army or navy surgeons are thus detailed, they shall receive no extra compensation, but their actual necessary traveling expenses shall be paid, for which vouchers shall be rendered They shall make full reports of their investigations to the Commissioner of Public Health

Sec 12 The Commissioner of Public Health may, with the approval of the Secretary of the Treasury and the President, and shall, on the requisition of the Secretary of the Treasury and the President, temporarily employ competent physicians to aid the Superintendents of quarantine during the invasion of an epidemic disease, and physicians thus temporarily employed shall receive compensation at the rate of $10 per day during the time of actual service, and their actual and necessary traveling expenses shall be paid, for which vouchers shall be rendered

Sec 14 The Commissioner of Public Health shall issue a weekly bulletin, for free distribution to all health boards and to the press of the country, containing an abstract of sanitary information in his possession that may be useful and interesting to the people He shall make an annual report to the Secretary of the Treasury, to be transmitted by him to Congress, containing a full account of all the transactions and expenditures of the Bureau The bulletin and report aforesaid, and all other necessary documents, shall be printed at the Government Printing Office, on the requisition of the Commissioner of Public Health, in the same manner and subject to the same provisions as other public printing for the several departments of the government

Sec 15 Any violation of the provisions of this act, or of the regulations authorized by this act, shall be punishable by a fine of not less than one hundred dollars nor more than one thousand dollars, or by imprisonment not less than thirty days nor more than one year, or by both such fine and imprisonment, in the discretion of the court The district courts and the prosecuting attorneys of the United States are hereby required to take cognizance of offences arising under this act, within their several jurisdictions

Sec 16 To defray the expenses incurred in carrying out the provisions of this act, the sum of $400,000 or so much thereof as may be necessary, is hereby appropriated, to be disbursed under direction of the Secretary of the Treasury, on the requisition of the Commissioner of Public Health

Sec 17 An act entitled "An act to prevent the introduction of contagious and infectious diseases into the United States, and to establish a National Board of Health," approved March 3, 1879, and all other acts or parts of acts conflicting with the provisions of this act, are hereby repealed

Sec 18 This act shall be in force on and after its passage and publication

FOREIGN CORRESPONDENCE.

LONDON LETTER.

London, December, 1884

Dr Arnold Royle, who was the private medical attendant of the late Duke of Albany, has been appointed "Gentleman Usher, Groom of the Privy Chamber, and Clerk of the Robes" to the Queen The post is a sinecure and is worth about £280 a year Dr Royle has certainly earned the Queen's favor, for his late post was a most arduous and difficult one to fill

Three years ago, the Rev Canon Erskine Clarke founded the Bolingbroke House Pay Hospital, which was intended for the reception of patients of the lower middle classes, and particularly for those who had fallen sick in lonely lodgings They were to be received upon paying such a reasonable portion of their actual cost as the means of the patient allowed It is obvious that by this means such an institution would be serving two very great objects, viz, the medical treatment of those who were willing to pay their utmost, instead of seeking free medical advice at one of the general hospitals, and enabling them to take in a great number of really poor, necessitous cases Hitherto this useful experiment has been conducted with the aid of an active local medical staff, but as this was thought to somewhat limit the usefulness of the hospital, the institution has now been thrown open to any qualified medical man who may wish to send in cases that need hospital treatment Although conducted on strict hospital principles it may be described as "a home within a hospital" Servants paid for by their masters or mistresses are received at one guinea weekly, and this is a very useful branch of the hospital's work

At a meeting of the Cambridge Medical Society an interesting case was brought to notice, of a man aged 50, robust and of temperate habits, who for the last twenty-five years had suffered from paroxysmal attacks of great pain in the epigastrium These increased in frequency and severity, chiefly during defœcation Sometimes the process lasted from one to three hours, during which he had frequent recourse to brandy and laudanum, at the conclusion he usually passed a few drops of glairy mucus from the bowel, with the simultaneous shedding of a few tears When seen during the paroxysm, his countenance was pallid, and bathed with perspiration, expressing agony His death occurred suddenly, previously he was very restless and exhausted At no time were there any physical signs The necropsy revealed a hard substance near the centre of the pancreas The head appeared natural, but, extending from about the middle of the body, a line of prominences could be seen running along the long axis to the tail, accompanied by great structural change Some of these masses were very pointed, denuded, and projected under the areolar tissue and peritoneal covering The lower part consisted of one amorphous mass of concretion, without any soft gland-structure Close to the sharp points the peritoneum and wall of the stomach were acutely inflamed, but there was no effusion The concretions consisted of carbonate and phosphate of lime The scantiness of the literature on pancreatic concretions was alluded to The emotional phenomena were thought to be due probably to reflex irritation of the alimentary canal, and the sudden death referred to the injury of the peritoneum by the sharp projections At the same meeting the case of a lady aged eighty was mentioned, in whom for upwards of fifteen years symptoms of intermittent pain at the epigastrium, with emotional phenomena existed, and at the post-mortem examination there was found a spindle celled sarcoma of the head of the pancreas, but no concretions

A lecture entitled "A Healthy Skin" has been delivered by Mr Startin, house surgeon to the St John's Hospital for diseases of the skin The lecturer said nothing was so likely to preserve us from cholera and from every other disease of an epidemic and contagious kind as a proper and constant care of the skin Mr Startin also dwelt upon the importance to health of a careful attention to diet English people, as a rule, took too much and too stimulating food, and would be the better for a more mixed and vegetable diet He condemned also entirely the use of spirits, except as a medicine The question of clothing was also of great importance in relation to the preservation of health Clothes should not be worn tight, and should be of such material as would convey from the skin the matter transpired The best material for wearing next the skin was white flannel, or as an alternative, merino Red flannel should never be worn, and his audience was warned to avoid all colored fabrics next the skin

Dr W N Thursfield, at the conference held under the auspices of the Society of Medical Officers of Health, on "The Spread of Infection through the Agency of Milk," said that the use of milk by adults had of late enormously increased, and although he could not but consider that to drink milk as a beverage with heavy meals was a grave dietetic error, the modern practice of drinking glasses of milk instead of beer at railway refreshment bars, etc, was not to be condemned To prevent milk epidemics precautions were necessary He recommended boiling of milk, as it was a well-known fact that consumers of boiled milk had invariably escaped in all epidemics

Dr Wood, the inventor of the hypodermic syringe, died lately at his house in Edinburgh In 1855 he drew attention to his new method of treating neuralgia by subcutaneous injection He was one of the former lecturers on The Practice of Medicine at the Royal College of Surgeons, and President of the Royal Medical Society

A course of six lectures will be delivered during this year at the London Hospital by Mr Jonathan Hutchinson, as Emeritus Professor of Clinical Surgery, on subjects of interest to house surgeons and dressers Members of the profession will be admitted to these lectures At a meeting of the committee formed to consider the best means of commemorating the name of Dr Rabbeths and the sacrifice he made of his life in the attempt to save a child's life suffering from diphtheria, it was resolved to establish a memorial medal at the University of London, bearing Dr Rabbeth's name, and a similar medal or scholarship at King's College The endowment of a child's cot at King's College Hospital and the Royal Free Hospital, and the erection of memorial tablets in the same building, were also resolved upon

There have just been removed by death two rising medical men, both already well known for their various accomplishments The first was Dr Mahomed, of Guy's Hospital, at the early age of 39, of typhoid fever, the other, Dr Llewelyn Thomas, after three days' illness of acute nephritis, at the age of 36 Dr Thomas acted some years at the Guest Hospital, Dudley, and then settled in London as a specialist in diseases of the throat and ear He was surgeon to the Central London Throat and Ear Hospital and to Trinity College, London G O M

BERLIN LETTER

BERLIN, Dec 1, 1884

The Treatment of Syphilis by Massage—Pellaterine in the Treatment of Tapeworm—Professional Notes—For pay patients in his private hospital Dr Lassar has inaugurated a routine treatment in all cases of syphilis In his poli klinik the poor people receive much the same attention, only in a less elaborate way, and specific medication is given by hypodermic injections of the mercuric bi-chloride The well-to do case of specific disease is first put into a tub of water as hot as it can be tolerated A strong nurse then gives him massage in the tub, and out of the water unguentum hydrargyri is rubbed in The patient is then put into a sweat bed, and hot teas or pilocarpin administered Then iodide of potassium and sarsaparilla tea, the latter to keep the skin active, Dr Lassar's theory of massage being, to render the lymphatic system more active in expelling the virus, and to place the skin in such condition that it can ably second the endeavor The masseur, anointing his hands with vaseline, begins first with the arms, which are rubbed quite forcibly in a direction from the wrist to the shoulder, then, with the thumb and forefinger of each hand encircling that member in so far as is possible, an "eccentric" motion is commenced, the two fingers of the one hand rotating toward the body, while the motion with the other hand is just the reverse, or away from the body of the masseur Then, grasping the hand of the patient, the arm is extended, rubbed, kneaded, and passive motion is kept up for a few moments The trunk receives the same attention, also the extremities, only instead of the "eccentric" motion, there is a slapping diversion, and a larger attention given to the deep kneading of the muscles Dr Lassar is having excellent results, but whether *post hoc* or *propter hoc*, I am unable to say In connection with specific treatment massage has much to commend itself to the attention of physicians How far its practice could obtain outside of a private hospital, remains to be seen In Dr Lassar's perfectly arranged and extensive sanitarium there is every facility for elaborate technique and investigation The expense incident to the sustaining of such an institution must be great, and only possible with men in *very* large and remunerative walks of life The use of pellaterine (the alkaloid of the pomegranate) has sprung suddenly into popularity here, owing to the immediate and entirely satisfactory effects arising from its administration Its excessive *cost* militates against its general use Not long ago, Hegar, of Fribourg (*Prager Med Wochenschrift*, No 26, 1884) published an article, "a new method of diagnosing with certainty, pregnancy in the early months" This consisted in a certain softness, pliability and tenuity of the inferior segment of the uterus—that is to say, of that part of the womb immediately superior to the insertion of the utero-sacral ligaments Dr Schroeder, in his lecture to the students on Nov 21, stated that for years he had found one sign of pregnancy in the early months, to be invariably certain, and then went on to give the details exactly as published by Hegar There have been several cases lately of women with highly exaggerated scoliosis in full term of pregnancy In every instance, however, except in one case at Charité, service of Prof Gusserow, the spinal deformity had not interfered with the normal pelvic measurements

Of laparotomies there seems to be no end Prof Schroeder is constantly opening the abdomen, and his gross results are admirable He makes a diagnosis rapidly, operates easily, and with the perfect self-possession that comes of varied experience There are very many points in medical education and procedure at Berlin which arrest the attention of an American It must be a rare phenomenon to find a German holding the University degree who has not something of scientific merit, and of clinical experience The opportunities for the *student* here to perfect himself in the practical details of his calling, such as frequent gynæcological examinations, obstetrical work (the application of forceps, craniotomy, etc), eye and ear operations, the opportunities for following up the clinical histories of patients, and for pathological investigation, are far ahead of anything at home I know of no college in the United States where a student can obtain so much practical experience in gynæcology and obstetrics as they can here Over two thousand cases yearly of labor are attended by students, and quite as many in the gynæcological department are examined by them Then the knowledge of pathology which seems indigenous to the German medical people is simply astonishing Even the least among them can go to the *fons et origo* of any case under discussion This is not a superficial knowledge, but a deep, logical ratiocination which is the outcome of years of study It is a concomitant fact of the German character, which is not satisfied until it has reached the beginning They are not diffuse They never attempt too much They *exhaust* one subject before attempting another Their pathology is the grand, massive foundation, upon which everything else must rest, and I cannot but wish that we had more of it Every day I have cause to blush for my own shortcomings in this way But in saying this much, I have said nearly all

The post-graduate courses in New York and elsewhere are much more satisfactory to the medical man than are any of the poli-kliniks here There are no clinics in the world, on the eye, better than those of Knapp, Agnew, Derby, and others The same may be said of the gynæcological courses of Munde, Dawson, Baer, Dudley, and men of equal eminence in other leading cities at home In practical didactic lectures, Emmet and Thomas, Goodell and Byford, Parvin, Palmer, Reamy, Flint, Bartholow, Minot and Whittaker cannot be excelled here, even if they be equalled All of our specialists, it seems to me, do certainly as good work and in a much neater fashion than is the custom here It is certainly well for the specialist to see different methods of operating, and it enlarges his general views, but for actual study our poli-kliniks are much superior—except in histology and pathology It is somewhat a matter of speculation in Berlin, and the return for one's money is not great *Le jeu ne vaut pas la chandelle* I am confining myself more to the case of *medical men* and not to students If one is fortunate enough to make some arrangement with one of the assistants he can often get much more *real* knowledge than he can from the more distinguished professor Such a course is that of Dr Weyder (first assistant to Prof Gusserow), who, for 20 marks, gives an admirable course to physicians on obstetrics, forceps, operations, etc In addition to this he is a very genial, courteous, warm-hearted man But these are characteristics of Dr Gusserow himself and of all of his assistants Not as much may be said of some of the others Landau's clinic covers the average cases that would come into the office of a general practitioner, but the amount of his material is small, his operations very, *very* rare, and his fee of 50 marks for four weeks somewhat excessive

The very general use of chloral-chloroform, and the recklessness in its administration is a matter of universal comment Scarcely an examination is made without the use of this anæsthetic A patient is often kept for an hour under its influence while the professor discusses her case before the students Barduken lost three cases and Bergman one case in one semester from chloroform narcosis The good results from primary surgical operations are largely due to strict antiseptic detail, for in manner, method, appliance and detail our surgery is finer, cleaner, and more ingenious Some of the mechanical devices in use, especially in gynæcology, are extremely clumsy and cumbersome I cannot imagine German manners of examination, and German methods being carried out at home They would scarcely be tolerated, and would be abhorrent to the greater sensitiveness of our women, even of the most debased So far as my observation goes, we do very much better gynæcological work in the United States than is done in Berlin, and nowhere can a medical man see better work upon the eye, or have more extended facilities for observation than in New York For the special histology of the normal eye, Moorfield's, London, Eng , is the best and only place I know There is no such course given here Two matters in surgery have impressed themselves upon me since my arrival in Berlin, with convincing force—one is that the intra-peritoneal treatment of the pedicle is the most correct one, and that there is a wide and growing field for conservative gynæcology This is dangerous ground for a man with hobbies, and I may not traverse it, lest I become prolix Suffice it to say that I am very strongly of the opinion that many cases would do better but for meddlesome interference—that the surgeon's skill is too often called into service, and that extirpation of the uterus, by any method, for malignant disease, exposes the patient to a terrible risk, and is but tentative in its results There is much special and general surgery here—much that is good and necessary, much that is unnecessary, and some that is bad I do not consider it good work to amputate the anterior cervical lip for a simple hypertrophy, not excessive and not accompanied with symptoms of bodily disorder I do not consider it necessary to operate upon a woman 68 years of age for a malignant orbital tumor, when the result of such operation will be fatal in the great majority of cases I do not consider it wholesome gynæcology to sew up every lacerated cervix, to dilate in every uncomplicated case of endometritis, to operate in every instance of fibroma, of myoma or carcinoma, or to use intra uterine injections of strong, saturated liquors of iron, iodoform or iodine as frequently as I have seen them used I *despise* pessaries, and most of all the big, unwieldly ones that are the fashion here It is not uncommon among some pro fessional men here to feign a disbelief in the efficacy of any method not purely of Berlin origin, and to cling with fanatical clanishness to unwieldly devices simply because they are indigenous If our German brothers can teach us pathology, histology, and exactness in examination, which they certainly can do, they can learn much from us in elegant surgery, in light and effective mechanical devices, and in conservative practice H R B

Charles W Shumway, m d , for nearly 30 years an active and respected practitioner of this city, died on the 19th inst , from diabetes

DOMESTIC CORRESPONDENCE

SECTION ON DISEASES OF CHILDREN.

Dr N S Davis, Editor Jour Am Med Asso , Chicago, Ill

Dear Sir—Will you, through the columns of the Journal, please request those who intend reading papers before the "Section on the Diseases of Children" to be kind enough to send the title of their papers, by the last week in March, to the Secretary of the Section, Dr S S Adams, Washington, D C , or to me, at Marshall, Texas

It is necessary to know the titles of the several papers to be presented, so that the committee of arrangements may be informed at least one month before the meeting of the Association, the last Tuesday in April, and we trust that no one will fail to notify us in due time Very respectfully,

John H Pope,
Ch'm'n Sec on Dis Child , Am Med Ass

NECROLOGY

Reed, Joseph Allison, m d , of Dixmont, Allegheny county, Pa , was born in Washington, Pa , December 31, 1823, of Scotch-Irish parentage, and died November 6, 1884

He received his classical education at Washington College, Pa , where he graduated a m in 1842, after which he began the study of medicine in the office of Julius Le Moyne, m d , the noted abolitionist of Western Pennsylvania, receiving his degree of m d from the Jefferson Medical College in 1847

Shortly after he located in Allegheny City, where he in a short time established himself in a large and lucrative practice Having a special aptitude for the study and treatment of mental diseases, he was, upon the establishment of the insane department of the Western Pennsylvania Hospital, at Pittsburgh, in 1854, chosen physician in chief

In 1857, the hospital having in the meantime been set apart exclusively for the care of the insane of the western district of Pennsylvania, Dr Reed was appointed resident physician and superintendent

Upon taking charge of the hospital it contained within its wards twenty-three patients, was in debt, and affairs were in the worst possible condition With characteristic promptness and energy he soon raised the amount necessary to relieve the institution from debt, and provide food and clothing for the starving inmates, in a short time placing the institution on an equal standing with others of the same class

Through his efforts and those of the widely-known philanthropist, Miss Dix, appropriations were obtained from the Legislature for the construction of a new hospital, to be located seven miles west of Pittsburg, on the north bank of the Ohio river, and under his immediate supervision the present exceptionally commodious edifice at Dixmont was erected

Upon the completion of the centre building and two adjacent wings in 1862, he removed the one hundred and thirteen patients then under his care into the new hospital

The building was subsequently enlarged by the addition of four wings, making the capacity of the institution six hundred From Dr Reed's last annual report we learn that since the opening of the hospital there have been under his care four thousand six hundred and ninety patients, of whom one thousand three hundred and ninety-six have been entirely restored, and one thousand two hundred and thirty very much improved in their mental and physical conditions

To his untiring efforts, unceasing devotion and indomitable energy is due the success of this his life work, and it stands a veritable "Arc de Triomph" to his memory A nobler memorial in this world is not to be desired

Dr Reed was a member of the County, State, and National Medical organizations, Association of Medical Superintendents of Insane Hospitals, American Social Science Association, and American Academy of Medicine

He was also a member of the commissions appointed by the legislature to superintend the erection of the Danville Hospital for the Insane, and to report on the care of the criminal insane

He was one of the committee appointed by the American Social Science Association to report on the proper provision for the insane, and a member of the commission appointed by Gov Hoyt to revise the lunacy laws of the State

In the death of Dr Reed the commonwealth loses one of its foremost alienists, and the medical profession one of its most distinguished members, a man endowed by nature with rare qualifications of mind, heart and soul, with unusual executive ability and wonderful skill in ministering to minds diseased

Possessed of remarkable personal magnetism, all those with whom he came in contact were irresistibly drawn towards him, and his patients were made to feel that in him they had found a *friend* as well as physician The secret of this lay in the strong, tender and loving sympathy of his spirit, which made him indescribably winning

I should not be doing full justice to the character of Dr Reed if I failed to speak of the strong religious sentiment which pervaded and influenced every act of his life

To know and confer with such a man was a rich privilege, and by his death earth is the poorer and Heaven the richer At a meeting of the Board of Managers of the Hospital, held shortly after his death, the following preamble and resolutions indicative of the high esteem in which he was held by those who knew him well, were adopted

WHEREAS, God, in the exercise of his sovereign will and wise providence, has removed by death Joseph A Reed, M D, who for years was Superintendent of the Western Pennsylvania Hospital for the Insane, the Executive Committee desire to place upon the records of the hospital the appreciation of his official character and its sorrow for the loss the hospital has sustained by his death

Therefore *be it Resolved*

First That in the judgment of the Committee the great ability and faithfulness exhibited by Dr Reed, gave him a place among the most prominent of those occupying similar positions in our land

Second The Committee has always had the satisfaction of knowing that the sacred interests which it was called upon to supervise—in the care of Dr Reed—were in the hands of one qualified by professional skill, executive ability and moral elevation of character to counsel it in the best possible manner

Third The Committee reflects with pleasure upon the fact that during the illness of Dr Reed it made known to him the high appreciation of his work, and its great sympathy for him in his sufferings, informing him also of the action of the Committee on October 30, which provided for his relief from all care, thus opening every avenue, as was hoped, for his recovery

Fourth That in the death of Dr Reed the hospital has lost an able superintendent and the charities of the State a most earnest and efficient promoter

R C Loomis, Sec , F S Bissell, Chairman

Dugas, Louis Alexander, M D , L L D , of Augusta, Ga , was born in Washington, Wilks Co , Ga , January 3, 1806, died at his residence in Augusta, October 19, 1884 He was of French extraction, his parents coming to Georgia from St Domingo, West India Islands After acquiring a good academical education he began the study of medicine in the office of Dr John Dent He attended medical lectures at the University of Pennsylvania, and at the University of Maryland, receiving his M D degree from the latter in 1827 Doctor Dugas then went to Europe, where he further prosecuted his studies in the large hospitals of Paris and London Returning to the United States he settled to practice in 1831, in Augusta In 1832, he and five associates formed the medical college of Georgia, in which institution he held a chair (and was Dean of the faculty,) to the time of his death He was for many years editor of *The Southern Medical and Surgical Journal* His contributions to medical literature are numerous and to be found in the various medical periodical publications of this country from 1831 to 1883 Although a general practitioner his taste led him to prefer surgery He also contributed valuable papers to the Georgia State Medical Association (of which he served as president for one term) and to the American Medical Association Dr Dugas became a member of the American Medical Association in 1847, attended 1849 and 1879 He was one of the vice-presidents of the International Medical Congress, held at Philadelphia in 1876 He was from the opening of the Augusta City Hospital one of the attending surgeons, President of the Academy of Richmond Co , and a member of a long list of learned and scientific societies at home and abroad He served with reputation as a surgeon during the war between the States

Doctor Dugas was a popular teacher, beloved by co-professors and by students He was twice married, first to Mary C Barnes, in 1833, her death occurred the same year In 1840 he was united in marriage to Louisa V Harris, daughter of Rev Uriah Harris, of Columbia, Ga

At a special meeting of the faculty of the Medical College of Georgia, feeling resolutions of respect for the worth and memory of Prof Dugas, were passed, and entered upon the minutes and published in the daily papers

His funeral was largely attended by a host of friends J M T

BOOK REVIEWS.

DOCTRINES OF THE CIRCULATION By J C DALTON, M D Cloth, 296 pages Philadelphia Henry C Lea's Son & Co

This history of physiological opinions and discovery, in regard to the circulation of the blood is, as far as we are aware, the most complete work upon the subject It is written in the most charming style and is abundantly backed up by an appendix containing quotations from the ancient writers To those who wish to read a good book or review their Greek, special advantages are offered by this volume Neither is the review of the subject untimely In fact, a passing glance at the history of great events is seldom untimely, for by observing the laborious research and heated argument which extending over periods of years finally result in the establishment of to us every day doctrines, we can better appreciate the labors of those patient workers of to day, who are by research and thought laying new foundations for future generations C E W

TRANSACTIONS OF THE MEDICAL ASSOCIATION OF GEORGIA 1884 Cloth Pp 477

This society has succeeded, by inserting a number of advertisements, in getting up its report in very good shape Among the most interesting matters we note the following That myopia is increasing among the Southern negroes as a result of book study, that woolen yarn makes an excellent vaginal tampon, that the coloring of urine with hydrochloride of rosaneline facilitates the recognition of pathological elements in the sediment, also, in a paper by Dr Jas M Hale, it is shown that extreme age is no contra-indication for cataract extraction Dr Eugene Foster, in a lengthy and able paper, reviews the opinions of Herbert Spencer respecting syphilis as a sociological problem Spencer claims that the disease in question is on the decrease, both as to the number of its victims and the virulence of the attack Dr Foster, like every other thoughtful and observant physician, is fully aware of the error of this assumption It may be true that the malignity of the disease is lessened, but this is probably the result of its successful treatment, rather than any change in the nature of the disease itself As a factor in social affairs, it is evident that Mr Spencer greatly underestimates the importance of syphilis C E W

TRANSACTIONS OF THE MEDICAL SOCIETY OF THE STATE OF WEST VIRGINIA SEVENTEENTH ANNUAL SESSION Paper 154 pages

This comprises numerous reports and contributions Dr R W Hall, after a discussion of the effects of great irregularities of the surface on atmospheric changes concludes, that during that part of the year in which the surface of the country is cooler than the atmosphere, there must be conditions very favorable to the development of diseases affecting the respiratory organs and such other diseases as are influenced by sudden changes of temperature

In connection with the report of a case of œsophagotomy by Fleming Howell, M D, for the removal of a silver half dollar, it is interesting to note that that coin seems to about measure in its diameter the maximum distensibility of the organ, moderate force being sufficient to introduce it beyond the convenient reach of instruments, the subsequent spasm of the œsophagus rendering operation necessary

Dr W H Sharp presents a lengthy review of the literature and opinions of the profession on the subject of Listerism in Obstetrics C E W

MISCELLANEOUS

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY, FROM JANUARY 10, 1885, TO JANUARY 16, 1885

Head, Jno T, Colonel and Surgeon Retired from active service by operation of law, on Jan 9, 1885, under provisions of act of Congress approved June 30, 1882 (S O 7, A G O, Jan 9, 1885)

McKee, J C, Major and Surgeon Ordinary leave of absence still further extended four months on surgeon's certificate of disability (S O 6, A G O, Jan 8, 1885)

Bentley, Edwin, Major and Surgeon Leave of absence extended two months (S O 8, A G O, Jan 10, 1885)

Elbrey, F W, Captain and Assistant Surgeon Sick leave still further extended six months on surgeon's certificate of disability (S O 9, A G O, Jan 12, 1885)

Tremaine, W S, Major and Surgeon Relieved from duty at Fort Porter, N Y

Girard, A C, Captain and A Surgeon Ordered for duty at Fort Porter, N Y

Appel, D M, Captain and A Surgeon Ordered for duty at Plattsburg Barracks, N Y

Girard, J B, Captain and A Surgeon Ordered for duty as Post Surgeon, Fort Schuyler, N Y H

Havard, Valery, Captain and A Surgeon On being relieved at Fort Schuyler, authorized to avail himself of leave of absence (four months) (S O 8, Dept East, Jan 12, 1885)

PROMOTIONS

Lt Col John Campbell, Surgeon, to be Surgeon with rank of Colonel Dec 7, 1884

Maj R H Alexander, Surgeon, to be Surgeon with rank of Colonel Dec 7, 1884

Capt, Henry McElderry, Assistant Surgeon, to be Surgeon with rank of Major Dec 7, 1884

APPOINTMENTS

Jefferson R Kean, to be Assistant Surgeon, with rank of First Lieutenant Dec 8 1884

A CLINICAL LECTURE ON THE MECHANICAL TREATMENT OF POTT'S DISEASE

BY CHARLES F STILLMAN, M. S , M D , OF NEW YORK,

Clinical Professor of Orthopœdic Surgery in the Woman s Medical College of New York Orthopœdic Surgeon to the New York Infant Asylum

The first case we will consider to-day is this boy of nine years, who has had spondylitis for two years, and whose mother died of phthisis soon after his birth There is no history of traumatism so far as it can be elicited, and his step-mother states that her attention was first drawn to his condition by his complaints of pain He described this pain as passing from his back around the right hip to the front of the abdomer, and that the pain was not constant, but was felt more in the afternoon, after exercise She also noticed that he afterwards began to carry himself stiffly, and carefully avoided bending the spine, resting often in a stooping posture, with his hands upon his knees, thus transferring the weight of the head and upper extremities to the legs directly She also noticed, about this time, a protrusion, or "knuckle," as she termed it, in the median line posteriorly, and this became more noticeable if he bent forward He was then seen by the family physician who diagnosed disease of the lower dorsal vertebræ, and recommended a plaster jacket, which was applied during partial suspension This, for a few weeks, caused an amelioration of the symptoms, but as they began to increase it was removed at the expiration of six weeks and another applied The deformity was, however, not improved, as the kyphos was slightly larger than when the patient was encased in the plaster, and suspension, while it straightened the spine and caused the compensatory curves to disappear, did not seem to appreciably affect the knuckle itself

At intervals the jackets were removed and renewed, as the indications for change arose, but they did not effect a cure of the disease The effect of the jacket was, however, valuable in the sense that it was restrictive, that it afforded a degree of fixation which prevented the vertebral ostitis from proceeding so rapidly as to form abscess, and as it is thoroughly protective it should be used when better agents are not at hand

But in the case of this child the parents became dissatisfied with the effects of the jacket four months ago and requested a change in the method of treatment Upon placing him on a padded table in the position shown in Fig 1, and allowing the head and shoulders to hang over the edge, the parts meanwhile being carefully supported while descending, the knuckle itself is seen to decrease perceptibly in size and prominence, and the compensatory curves are reduced. This effect is due to gravitation, the head and upper extremities, hanging in space on a lower plane than the kyphos, act as a downward traction force upon it, while the padded edge of the table, by opposing resistance to the descent of the rest of the body, exerts a force, in a directly opposite direction, upon the kyphos itself The first causes an extension of the diseased portion, relieving local pressure and tending to stretch it into the normal curve of the spine, while the second intensifies the direct effect upon the kyphos in diminishing the deformity

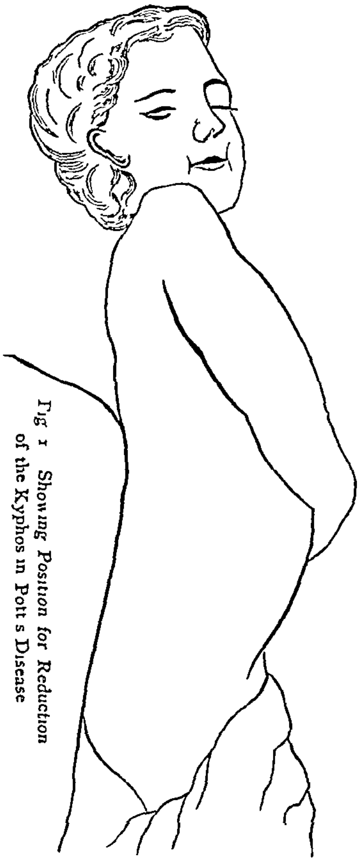

Fig 1 Showing Position for Reduction of the Kyphos in Pott s Disease

Authorities have so stoutly maintained that a knuckle, when once formed, should be allowed to proceed to complete consolidation, without attempting to mould the parts into better symmetry before the consolidation is effected, that it required considerable courage to first try the effects of this position, which would tend, to a certain extent, to disorganize the consolidation if not yet completed, and I was, therefore, very much pleased in my first case to note

ties by the other, traction force is exerted horizontally to separate the two attachments

Upon the principle of *vertical* traction are founded linear traction braces, a notable example being that of Prof Edmund Andrews, of Chicago, in which the extension is produced by a screw-ratchet, but very much more often a vertical suspension apparatus is employed

This is best known in connection with the plaster-of-paris jacket advocated so warmly by Prof Sayre, and which was exhibited to you in detail at our last clinic, when a jacket was applied

This suspension apparatus lifts a patient's superincumbent weight from the diseased portion, and utilizes as a vertical traction agent all that portion of the body below the seat of disease While thus suspended a plaster-of-paris bandage is rapidly and smoothly wound around the trunk and allowed to "set" firmly before the erect position is again assumed, with the object of holding the extension gained by the suspension But this has been demonstrated by Heather Bigg, Shaffer, and others, to be impossible, and the opinion is expressed by them that the spine, being grasped by the plaster only throughout part of its extent, is not held so as to prevent its segments from pressing upon one another when the vertebral column resumes its normal function of carrying the weight of the head and upper extremities The extension produced by the suspension is lost when the suspension ceases, unless a jury-mast is added to the jacket, in which case the extension produced by the suspension can be maintained by the apparatus If, however, the jury-mast is not used, the plaster jacket becomes a fixation splint, but is more effective than the other splints of the fixation class, because it holds the spine in the improved curves produced by the suspension There is, however, no possibility of adjustment or inspection of the parts, unless the jacket is removed and reapplied, and as there is no active force pressing forward upon the kyphos, there is no corresponding decrease in the actual deformity except such as may be gained at the time of each suspension, and, of course, a certain amount of this is lost if not all, when the spinal chain again becomes a column by the cessation of the suspension and the resumption of the superincumbent weight, which tends to press the diseased portions together

Symmetrical traction can also be exerted locally in the lower dorsal and lumbar regions, by dividing the jacket and connecting the segments by ratchets, but the use of such apparatus is unsatisfactory—for while vertical tension is exerted upon the soft parts between the segments, sufficient power cannot be employed to cause a state of extension between the vertebræ, without exciting too much pressure upon the skin and other soft structures—while at the same time no forward pressure is brought to bear upon the kyphos The action of vertical traction upon a kyphos is well illustrated by a long strip of lead or other flexible material in which a knuckle is formed in the semblance of the deformity of Pott's disease If linear traction is made to overcome this knuckle it will be seen that no power which can be exerted will take it out entirely, that although the strip becomes straight on either side of the angle, the angle itself does not disappear, and it will therefore be readily understood that while the curves of the spine are similarly improved by linear traction, and can be held in this improved position by the plaster jacket, or a divided jacket provided with linear ratchets, it is impossible for the deformity itself to be completely overcome, or even appreciably improved by them, or any form of apparatus founded upon the principle of symmetrical traction

It, therefore, is apparent that although very little permanent improvement can be effected upon the deformity itself, unless it is very recent, yet the fixation in an improved position which they certainly secure, often arrests further progress of the disease and prevents increase of the deformity

These divided jackets first came into use in 1878, the idea originating with myself, and being published by me at that time, and my apparatus was afterwards improved by Dr Wyeth, of this city Still later Dr Roberts, also of this city, substituted elastic traction ratchets for the fixed traction ratchets of Dr Wyeth and myself, with the idea of producing a constant linear elastic force, which should admit of motion, but not otherwise altering the principles involved

Of more value, however, than symmetrical traction, in Pott's disease, is the *third* principle of mechanical treatment, which you will remember is the partial extension caused by *backward traction*

This produces extension of the bodies of the vertebræ relieving them from pressure by curving the spine backward, so that the articular processes are caused to assume the superincumbent weight The origin of this principle is generally ascribed to Dr H G Davis, although the first effective instrument for utilizing the principle was devised by Dr C F Taylor, and this was exhibited to you at the last lecture

A later instrument for the same purpose was invented and used by Mr Chance, of London, and has lately been advocated by E Noble Smith, although the difference between the original brace of Dr Davis and that of Mr Chance is so slight as to be hardly appreciable, but the latter is extended upward so as to embrace a greater extent of the spine, which is a point of advantage Dr Taylor's brace differs from the others in being provided with a double screw hinge, placed just above and below the kyphos, so that the angle of the upper with the lower portion could be changed by the screws without removal of the brace from the back, while in the others this alteration must be effected by a wrench or the hand before the brace is applied, but the action of each of them on the spine is the same

In all of these braces for backward traction, and in those for fixation and symmetrical traction beside, the *bending point* of the spine, or the point where the spine most readily gives way if the patient leans forward, is at the *seat* of *disease*, so that it requires great strength on the part of the apparatus to prevent this

You have thus seen and had demonstrated to you that the patient was not only not rendered uncomfortable by the proceeding, that no bad effects were observable, but that a mitigation of the pain at once took place, very much the same as is often observed, and has been referred to by others as resulting from placing a child with Pott's disease on the knees, with the kyphos between them and drawing the knees gradually apart In the patient before you the same result is obtained, both in regard to pain and disappearance of the compensatory curves, the kyphos, in addition, being also caused to decrease in size

The attitude assumed by the authorities who urge that consolidation should take place without attempting to previously reduce the deformity, is very similar to that which was formerly maintained in regard to the hip—that ankylosis in the flexed and adducted position was the proper and best result attainable, and should be encouraged At the present time, however, as we have aimed to show in the consideration of the hip cases treated in our clinic, we are not satisfied with ankylosis and deformity, but try to effect motion and absence of deformity, and gradually restore the joint to a useful condition To a certain degree this applies to the spine

The pathological progress of ostitis in the head of the femur and in the bodies of the vertebræ is very similar, and if in hip disease we can prevent the deformity from becoming permanent until the ostitis is arrested and the function of the joint restored, we might with reason claim that if the vertebræ can be prevented from being crushed together by the superincumbent weight while they are in the soft and disintegrated condition incident to the ostitis, until the disease is overcome and the process of repair completed, a cure could be effected without deformity Proceeding still further, it is also reasonable to suppose that while the carious process is still active and consolidation not effected, although a kyphos may be present when the erect position is assumed, owing to the pressure of the superincumbent weight, if this kyphos can be *immediately* reduced, and the reduction maintained by a splint until the active stage of the ostitis has ceased and the process of repair is complete, or if the kyphos can be *gradually* reduced, day by day, by the use of an active force embodied in the splint, which is so constructed as to gradually overcome the deformity, and also to maintain such reduction independently of any position which the body can assume, and at the same time fix the entire spine in a position which tends to keep the bodies of the vertebræ from being pressed together by the superincumbent weight, it would follow as a natural result that a cure without deformity would ensue Of course, force sufficient to break up consolidation which is actually complete, should never be employed There is no need for me to point out the dangers or disastrous consequences of such a proceeding, but we are merely referring to the use of the gentle and efficient traction which can be exerted by the weight of the part above the seat of deformity, when exerted as already described

In the case before you this plan of treatment was strictly followed, but to understand fully the principles upon which the treatment of this case was based, it will be necessary to discuss the subject more in detail

In our last lecture we considered the various methods of treatment for this disease which were in vogue, and demonstrated the principles upon which they were founded You will remember that when we considered the mechanical department of the treatment, we divided it into three classes

1 Simple fixation,
2 Symmetrical traction, and
3 Backward traction,

because all the braces and splints for Pott's disease were based in their action upon one of these three principles

Bearing in mind, as has been ably pointed out by Heather Bigg, that the spine is a column composed of many segments, which are in apposition when the superincumbent weight is borne upon it, but that this column becomes a chain when force is exerted, or a posture assumed, which tends to draw these segments apart, it will be seen that the attempt to produce fixation of such a flexible undulating column is attended with serious mechanical obstacles You will remember, in describing the different forms of apparatus to produce simple fixation (and among these were the braces of Andrews, Washburne, Knight and others, the plaster zone of Shaffer, the wire cuirass of Bauer, and the firm jackets of Vance, Steele and others), they were described as attempting to enforce rest for the diseased portion, either by means of long metallic strips placed upon either side of the spine posteriorly and held there by girths and straps, or by enclosing the trunk in splints of leather, plaster-of-paris, felt, or other firm material, which are removable, and are usually laced tightly anteriorly, or a combination of the metallic frame and plaster-of-paris, as in the Shaffer brace But in all the forms of apparatus which embody the principle of fixation, the material strength of the splint is opposed to the flexibility of the spinal column, and if the material were sufficiently strong it would tend to hold the spine firmly, and thus tend to limit the active stage of the ostitis and inaugurate the stage of repair

The fixation appliances, however, do not attempt to remedy the deformity or produce extension of the diseased part, and their range of usefulness is, therefore, more limited than those of the other classes

Now, *extension* of the spine may be of two forms 1st, complete or symmetrical, or, 2d, partial, and both are utilized in the mechanical treatment

Symmetrical extension of the spine is the form in which the bodies and articular surfaces are stretched by the traction force to the same extent, and differs from the *partial* extension produced by backward traction, in which only the bodies of the vertebræ are stretched, the pressure being transferred to the articular *facets*

Symmetrical extension is produced by traction exerted either *horizontally* or *vertically*

Upon the principle of *horizontal* traction are founded the various horizontal couches or frames in which the patient lies supinely, and, while the shoulders and head are embraced by one segment of the divided frame, and the pelvis and lower extremities by the other, traction force is exerted horizontally to separate the two attachments

Upon the principle of *vertical* traction are founded linear traction braces, a notable example being that of Prof Edmund Andrews, of Chicago, in which the extension is produced by a screw-ratchet, but very much more often a vertical suspension apparatus is employed

This is best known in connection with the plaster-of-paris jacket advocated so warmly by Prof Sayre, and which was exhibited to you in detail at our last clinic, when a jacket was applied

This suspension apparatus lifts a patient's superincumbent weight from the diseased portion, and utilizes as a vertical traction agent all that portion of the body below the seat of disease While thus suspended a plaster-of-paris bandage is rapidly and smoothly wound around the trunk and allowed to "set" firmly before the erect position is again assumed, with the object of holding the extension gained by the suspension But this has been demonstrated by Heather Bigg, Shaffer, and others, to be impossible, and the opinion is expressed by them that the spine, being grasped by the plaster only throughout part of its extent, is not held so as to prevent its segments from pressing upon one another when the vertebral column resumes its normal function of carrying the weight of the head and upper extremities The extension produced by the suspension is lost when the suspension ceases, unless a jury-mast is added to the jacket, in which case the extension produced by the suspension can be maintained by the apparatus If, however, the jury-mast is not used, the plaster jacket becomes a fixation splint, but is more effective than the other splints of the fixation class, because it holds the spine in the improved curves produced by the suspension There is, however, no possibility of adjustment or inspection of the parts, unless the jacket is removed and reapplied, and as there is no active force pressing forward upon the kyphos, there is no corresponding decrease in the actual deformity except such as may be gained at the time of each suspension, and, of course, a certain amount of this is lost if not all, when the spinal chain again becomes a column by the cessation of the suspension and the resumption of the superincumbent weight, which tends to press the diseased portions together

Symmetrical traction can also be exerted locally in the lower dorsal and lumbar regions, by dividing the jacket and connecting the segments by ratchets, but the use of such apparatus is unsatisfactory—for while vertical tension is exerted upon the soft parts between the segments, sufficient power cannot be employed to cause a state of extension between the vertebræ, without exciting too much pressure upon the skin and other soft structures—while at the same time no forward pressure is brought to bear upon the kyphos The action of vertical traction upon a kyphos is well illustrated by a long strip of lead or other flexible material in which a knuckle is formed in the semblance of the deformity of Pott's disease If linear traction is made to overcome th s knuckle it will be seen that no power which can be exerted will take it out entirely, that although the strip becomes straight on either side of the angle, the angle itself does not disappear, and it will therefore be readily understood that while the curves of the spine are similarly improved by linear traction, and can be held in this improved position by the plaster jacket, or a divided jacket provided with linear ratchets, it is impossible for the deformity itself to be completely overcome, or even appreciably improved by them, or any form of apparatus founded upon the principle of symmetrical traction

It, therefore, is apparent that although very little permanent improvement can be effected upon the deformity itself, unless it is very recent, yet the fixation in an improved position which they certainly secure, often arrests further progress of the disease and prevents increase of the deformity

These divided jackets first came into use in 1878, the idea originating with myself, and being published by me at that time, and my apparatus was afterwards improved by Dr Wyeth, of this city Still later Dr Roberts, also of this city, substituted elastic traction ratchets for the fixed traction ratchets of Dr Wyeth and myself, with the idea of producing a constant linear elastic force, which should admit of motion, but not otherwise altering the principles involved

Of more value, however, than symmetrical traction, in Pott's disease, is the *third* principle of mechanical treatment, which you will remember is the partial extension caused by *backward traction*

This produces extension of the bodies of the vertebræ relieving them from pressure by curving the spine backward, so that the articular processes are caused to assume the superincumbent weight The origin of this principle is generally ascribed to Dr H G Davis, although the first effective instrument for utilizing the principle was devised by Dr C F Taylor, and this was exhibited to you at the last lecture

A later instrument for the same purpose was invented and used by Mr Chance, of London, and has lately been advocated by E Noble Smith, although the difference between the original brace of Dr Davis and that of Mr Chance is so slight as to be hardly appreciable, but the latter is extended upward so as to embrace a greater extent of the spine, which is a point of advantage Dr Taylor's brace differs from the others in being provided with a double screw hinge, placed just above and below the kyphos, so that the angle of the upper with the lower portion could be changed by the screws without removal of the brace from the back, while in the others this alteration must be effected by a wrench or the hand before the brace is applied, but the action of each of them on the spine is the same

In all of these braces for backward traction, and in those for fixation and symmetrical traction beside, the *bending point* of the spine, or the point where the spine most readily gives way if the patient leans forward, is at the *seat of disease*, so that it requires great strength on the part of the apparatus to prevent this

You have thus seen and had demonstrated to you some of the typical forms of apparatus which are largely used by the profession for the treatment of spondylitis, and have seen several of them in successful operation, and we now proceed to the discussion and description of another and more recent form of spinal brace which embodies some valuable attributes not possessed by any of those enumerated

It has already been stated to you that if the patient bent forward while wearing any of the braces or appliances described, the spine was more apt to give way at the seat of disease than at any other portion of its extent, owing to the yielding character of the diseased osseous structure, and that this tendency was only combated by the strength of the material employed in the splints Now, this bending forward is one of the most important factors for increase of deformity and the retardation of cure, and to meet it successfully I have been obliged to use a lever or spring, which would bring a constant *forward* elastic power to bear directly and automatically upon the kyphos, and after considerable experience I am prepared to advocate a form of spring lever which meets *this bending tendency successfully*

If the disease is in the dorsal region, a brace is constructed so as to embody a lever with a short and a long arm, the short arm extending from the site of the disease to the sacrum, and the long arm from the neck to the sacrum, the two being there connected by an adjustable clamp, and together forming a V shaped lever, which automatically acts to press forward the deformity and yet hold the spine firmly in the erect position

The force is so graduated that if leaning forward is attempted, the shorter arms press firmly over the transverse processes adjacent to the kyphos, and exert a forward pressure which prevents the spine yielding at the seat of disease In no other brace known is this accomplished, and it thereby secures a greater degree of fixation than either of the braces or splints described If the lumbar region be involved, the short arm of the lever passes from the diseased part to the second dorsal vertebra, and the long arm from the sacrum to the same point, and they are there secured together by an adjustable clamp and connected to the front of the chest by straps and a T plate, the latter utilizing the infra-clavicular spaces and sternum as pressure points, thus preventing interference with or constriction of the soft parts The braces formed upon this lever plan afford fixation in the erect position and exert forward pressure at the seat of disease, and no posture of the patient can influence or derange the action of the instrument since it is compensatory

The other systems of treatment described in the course of our lecture have, with a few exceptions, been *before the profession for a sufficiently long* period to have their merits generally understood, and have been employed with a varying degree of success, but, on the whole, the mechanical treatment of Pott's disease is considered to be in an unsatisfactory condition There are two requisites which must enter into the consideration of this mechanical problem, if its treatment is to be attended with success, and these are 1st, arrest of the disease, and 2d, obliteration of the deformity

Nature herself points out the direction in which force should be applied to relieve the diseased bodies and produce curative results

Who among us has not noticed the position assumed by a patient with the disease in the stage of invasion? The body is held rigidly, the head and shoulders being thrown back as far as possible, and in stooping to pick up an object from the floor, this position is still maintained, the patient having every muscle exercised to hold the spine perfectly fixed and bent backward, the position being very much that of an equestrian "head and chest up, the shoulders held back, and the small of the loins well knit in" Were it possible for the patient to retain this position indefinitely, progress of the disease to the stage of deformity would be *almost impossible, but it is a natural* tendency in unguarded moments and for the purpose of resting the spine, to bend forward, and bending forward from any cause, removes the weight from the articular processes, and proportionately transfers it to the bodies of the vertebræ and their intervening cartilages The muscles are unable to continue supporting the spine in its hyper erect position at all times, and consequently the patient bending forward occasionally, causes increased pressure upon the diseased cancellous bodies, hastening absorption of their structure and the formation of deformity

Nature's indication for the treatment of Pott's disease is to put a splint on the back of the patient which will maintain this erect position, for since the tendency of the disease is to curve the affected portion of the spine forward, the center of this curve being anteriorly, our corrective force should be applied to produce exactly an opposite curve to the diseased one, the centre of such a corrective curve being posterior to the column In other words, we must *follow nature's lead and hold the spine erectly* and slightly curved backward, the tendency of the disease being to curve it forward, *and to thoroughly* understand the principle upon which the new brace for *this purpose is constructed, this patient* having a well-defined knuckle is again laid on his back upon a table, the padded edges of which come to the apex of the deformity, the shoulders and head being allowed to fall downward (See Fig 1)

You will observe as the patient's head and shoulders descend, that a partial, but physiological and true extension of the spine is effected, the traction force being all that portion of the patient above the seat of disease This augmented by gravity, produces a backward curve of the spine, most marked at the seat of disease There is also a *tendency to obliterate* the knuckle and this is only prevented from taking place entirely by such consolidation as has become perfected

We have thus produced by this position the two effects we consider to be necessary to successful treatment and have placed the spine in curves the reverse of those it held before this posture was assumed

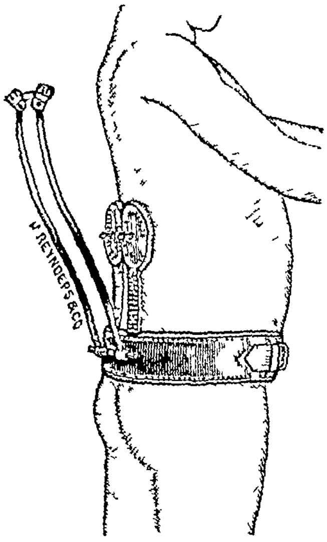

Fig 2 Showing Lever Brace for lower dorsal region before the long arm is strapped to the body the backward angle of the long arm being regulated by a clamp inferiorly

If this position could be maintained indefinitely there would be rapid improvement in the disease , but as this is obviously impossible we attempt to embody in a brace the forces involved, it being for this purpose constructed in two parts The "table" portion of the brace (and by this we mean that portion of the brace which is to produce upon the patient an effect identical with the table, as shown in Fig 1) consists of a firm pelvic band from which strong padded strips pass up on either side of the median line to the seat of disease (see Fig 2) and these form the short arm of the lever

The "backward traction" portion of the brace consists of a back frame secured on the pelvic girth by a ratchet or clamp which allows it to be adjusted at any outward angle, and thus regulates the amount of forward pressure upon the kyphos

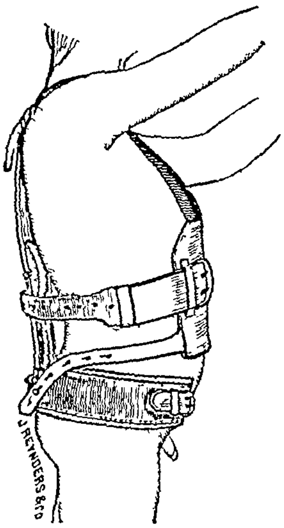

Fig 3 The same strapped to the body the pads there exerting forward pressure at the seat of disease

The angle at which this back frame, or long arm of the lever, is thrown out from the body (see Fig 2) determines whether the brace shall act as a lever or as a simple fixation brace, and the angle between the long and short arms determines the degree of power employed , and when the back frame is set outward at an angle with the short arm and is drawn down to the body and fastened firmly (as shown is Figs 3 and 4) the short arms terminating in the pads press forward upon the transverse processes of the diseased vertebræ with a constant elastic force

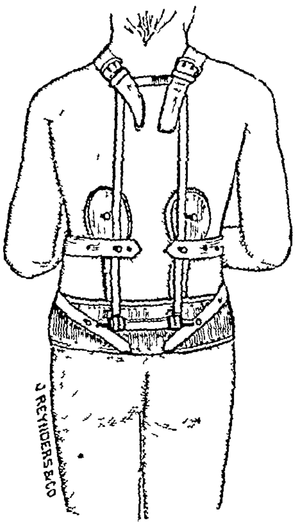

Fig 4 The same (posterior view) The position of the kyphos, if shown, would be between the two pads

There are also other features of this brace which deserve mention It will be observed that if the angle between the short and long arms of the lever is considerable when the long arm is fastened firmly to the body the bending tendency forward of the upper part of the trunk does not cause the spine to give way at the seat of disease, for in proportion as the patient leans forward the short arms press forward upon the kyphos, and oppose a resistance to the bending at that point, so that by the brace a curative automatic effect is produced to keep the body erect, and at the same time prevent further deformity while tending to improve that which already exists Also that the *spring* effect, produced by the setting off of the traction frame, and drawing it forward against the body which is thus held erectly when properly strapped, causes the brace to be held more tightly against the back and ensures a higher degree of fixation than any form of apparatus in use

In the beginning of the treatment it is well to have the traction frame set off at such an angle as to cause considerable pressure upon the transverse processes of the kyphos, and produce thorough extension of the diseased portion, but this angle may be lessened week by week as the case improves, until finally the traction frame lies directly upon the pads, and the brace becomes a mere fixation brace without any leverage whatever

To further illustrate the action of this brace, if a bent lead strip is taken and one extremity held firmly by one hand, with the thumb pressed against the knuckle, it will be found that a force comparatively slight (when contrasted with that used in linear traction to produce not so perfect a result) with the other hand will serve to straighten the rod into its original position, knuckle and all This is precisely what is accomplished by this brace We grasp firmly the lower part of the spine as high as the seat of disease, and then, by force applied above, bend the spine

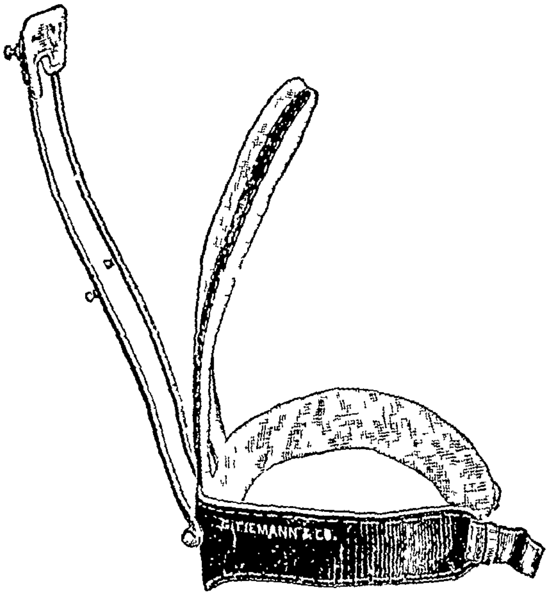

Fig 5 Showing lever brace for middle dorsal region, with straps removed

some of the typical forms of apparatus which are largely used by the profession for the treatment of spondylitis, and have seen several of them in successful operation, and we now proceed to the discussion and description of another and more recent form of spinal brace which embodies some valuable attributes not possessed by any of those enumerated.

It has already been stated to you that if the patient bent forward while wearing any of the braces or appliances described, the spine was more apt to give way at the seat of disease than at any other portion of its extent, owing to the yielding character of the diseased osseous structure, and that this tendency was only combated by the strength of the material employed in the splints. Now, this bending forward is one of the most important factors for increase of deformity and the retardation of cure, and to meet it successfully I have been obliged to use a lever or spring, which would bring a constant *forward* elastic power to bear directly and automatically upon the kyphos, and after considerable experience I am prepared to advocate a form of spring lever which meets this bending tendency successfully.

If the disease is in the dorsal region, a brace is constructed so as to embody a lever with a short and a long arm, the short arm extending from the site of the disease to the sacrum, and the long arm from the neck to the sacrum, the two being there connected by an adjustable clamp, and together forming a V shaped lever, which automatically acts to press forward the deformity and yet hold the spine firmly in the erect position.

The force is so graduated that if leaning forward is attempted, the shorter arms press firmly over the transverse processes adjacent to the kyphos, and exert a forward pressure which prevents the spine yielding at the seat of disease. In no other brace known is this accomplished, and it thereby secures a greater degree of fixation than either of the braces or splints described. If the lumbar region be involved, the short arm of the lever passes from the diseased part to the second dorsal vertebra, and the long arm from the sacrum to the same point, and they are there secured together by an adjustable clamp and connected to the front of the chest by straps and a T plate, the latter utilizing the infra-clavicular spaces and sternum as pressure points, thus preventing interference with or constriction of the soft parts. The braces formed upon this lever plan afford fixation in the erect position and exert forward pressure at the seat of disease, and no posture of the patient can influence or derange the action of the instrument since it is compensatory.

The other systems of treatment described in the course of our lecture have, with a few exceptions, been before the profession for a sufficiently long period to have their merits generally understood, and have been employed with a varying degree of success, but, on the whole, the mechanical treatment of Pott's disease is considered to be in an unsatisfactory condition. There are two requisites which must enter into the consideration of this mechanical problem, if its treatment is to be attended with success, and these are 1st, arrest of the disease, and 2d, obliteration of the deformity.

Nature herself points out the direction in which force should be applied to relieve the diseased bodies and produce curative results.

Who among us has not noticed the position assumed by a patient with the disease in the stage of invasion? The body is held rigidly, the head and shoulders being thrown back as far as possible, and in stooping to pick up an object from the floor, this position is still maintained, the patient having every muscle exercised to hold the spine perfectly fixed and bent backward, the position being very much that of an equestrian "head and chest up, the shoulders held back, and the small of the loins well knit in." Were it possible for the patient to retain this position indefinitely, progress of the disease to the stage of deformity would be almost impossible, but it is a natural tendency in unguarded moments and for the purpose of resting the spine, to bend forward, and bending forward from any cause, removes the weight from the articular processes, and proportionately transfers it to the bodies of the vertebræ and their intervening cartilages. The muscles are unable to continue supporting the spine in its hyper erect position at all times, and consequently the patient bending forward occasionally, causes increased pressure upon the diseased cancellous bodies, hastening absorption of their structure and the formation of deformity.

Nature's indication for the treatment of Pott's disease is to put a splint on the back of the patient which will maintain this erect position, for since the tendency of the disease is to curve the affected portion of the spine forward, the center of this curve being anteriorly, our corrective force should be applied to produce exactly an opposite curve to the diseased one, the centre of such a corrective curve being posterior to the column. In other words, we must follow nature's lead and hold the spine erectly and slightly curved backward, the tendency of the disease being to curve it forward, and to thoroughly understand the principle upon which the new brace for this purpose is constructed, this patient having a well-defined knuckle is again laid on his back upon a table, the padded edges of which come to the apex of the deformity, the shoulders and head being allowed to fall downward. (See Fig. 1.)

You will observe as the patient's head and shoulders descend, that a partial, but physiological and true extension of the spine is effected, the traction force being all that portion of the patient above the seat of disease. This augmented by gravity, produces a backward curve of the spine, most marked at the seat of disease. There is also a tendency to obliterate the knuckle and this is only prevented from taking place entirely by such consolidation as has become perfected.

We have thus produced by this position the two effects we consider to be necessary to successful treatment and have placed the spine in curves the reverse of those it held before this posture was assumed.

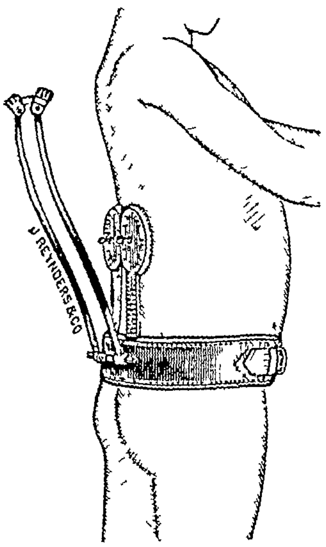

Fig 2 Showing Lever Brace for lower dorsal region before the long arm is strapped to the body the backward angle of the long arm being regulated by a clamp inferiorly

If this position could be maintained indefinitely there would be rapid improvement in the disease, but as this is obviously impossible we attempt to embody in a brace the forces involved, it being for this purpose constructed in two parts The "table" portion of the brace (and by this we mean that portion of the brace which is to produce upon the patient an effect identical with the table, as shown in Fig 1) consists of a firm pelvic band from which strong padded strips pass up on either side of the median line to the seat of disease (see Fig 2) and these form the short arm of the lever

The "backward traction" portion of the brace consists of a back frame secured on the pelvic girth by a ratchet or clamp which allows it to be adjusted at any outward angle, and thus regulates the amount of forward pressure upon the kyphos

The angle at which this back frame, or long arm of the lever, is thrown out from the body (see Fig 2) determines whether the brace shall act as a lever or as a simple fixation brace, and the angle between the long and short arms determines the degree of power employed, and when the back frame is set outward at an angle with the short arm and is drawn down to the body and fastened firmly (as shown is Figs 3 and 4) the short arms terminating in the pads press forward upon the transverse processes of the diseased vertebræ with a constant elastic force

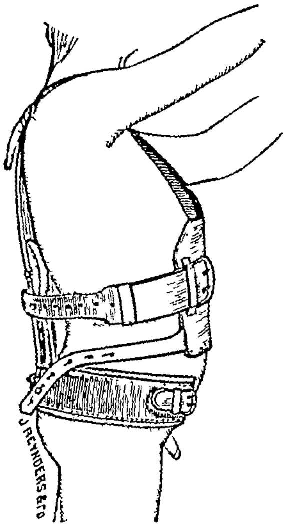

Fig 3 The same strapped to the body the pads there exerting forward pressure at the seat of disease

There are also other features of this brace which deserve mention It will be observed that if the angle between the short and long arms of the lever is considerable when the long arm is fastened firmly to the body the bending tendency forward of the upper part of the trunk does not cause the spine to give way at the seat of disease, for in proportion as the patient leans forward the short arms press forward upon the kyphos, and oppose a resistance to the bending at that point, so that by the brace a curative automatic effect is produced to keep the body erect, and at the same time prevent further deformity while tending to improve that which already exists Also that the *spring* effect, produced by the setting off of the traction frame, and drawing it forward against the body which is thus held erectly when properly strapped, causes the brace to be held more tightly against the back and ensures a higher degree of fixation than any form of apparatus in use

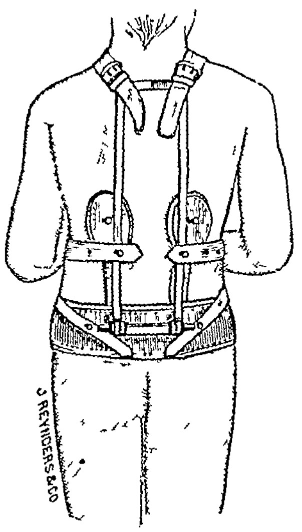

Fig 4 The same (posterior view) The position of the kyphos, if shown, would be between the two pads

In the beginning of the treatment it is well to have the traction frame set off at such an angle as to cause considerable pressure upon the transverse processes of the kyphos, and produce thorough extension of the diseased portion, but this angle may be lessened week by week as the case improves, until finally the traction frame lies directly upon the pads, and the brace becomes a mere fixation brace without any leverage whatever

To further illustrate the action of this brace, if a bent lead strip is taken and one extremity held firmly by one hand, with the thumb pressed against the knuckle, it will be found that a force comparatively slight (when contrasted with that used in linear traction to produce not so perfect a result) with the other hand will serve to straighten the rod into its original position, knuckle and all This is precisely what is accomplished by this brace We grasp firmly the lower part of the spine as high as the seat of disease, and then, by force applied above, bend the spine

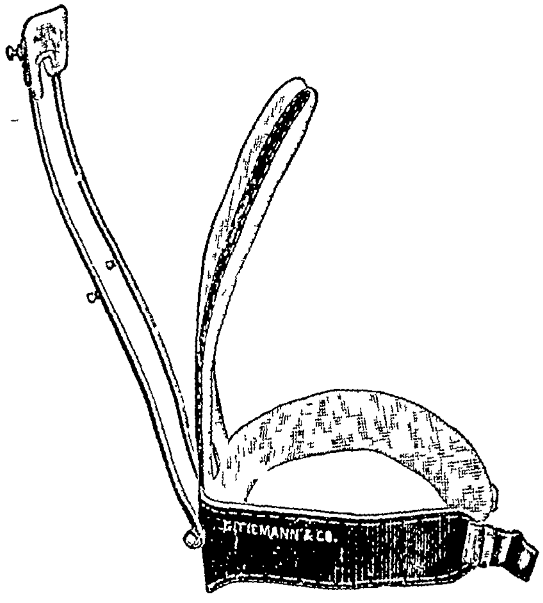

Fig 5 Showing lever brace for middle dorsal region, with straps removed

backward sufficiently to relieve the bodies of the vertebræ from pressure, and at the same time with the short arm of the lever, corresponding to the action of the thumb upon the lead strip, press forward upon the deformity, and thus, by the use of a very light frame-work, we can exert sufficient leverage to retain the spine in the erect position of the equestrian, and as this *backward* force is distributed along the entire dorsal and lumbar spine, while the *forward* pressure is exerted only along the spine from the seat of disease downward, decreasing from the kyphos to the sacrum, it will be found that no injurious pressure is exerted at any one point, as is the case in the Taylor or Chance braces

For the middle dorsal region the short arms of the lever are longer than in the lower dorsal, so as to be opposite the seat of disease, and the brace may be attached by straps, as shown in Figs 5 and 6

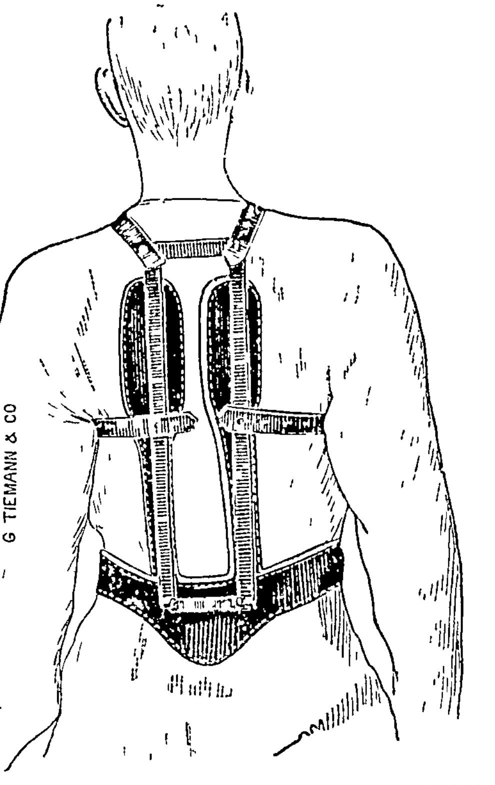

Fig 6 The same (posterior view), after attachment to the body

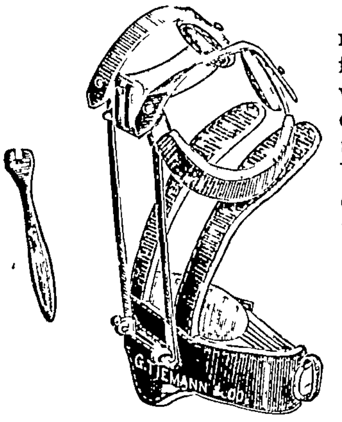

Fig 7 Showing lever brace for upper dorsal region, with infra clavicular pads instead of thoracic straps, for attachment to the body

For the upper dorsal region the straps in front are dispensed with, the attachment of the long arm of the lever superiorly being effected, by padded strips, curved so as to pass under the axillæ and terminating in infra-clavicular pads, which are still better retained in place by straps over the shoulder (as shown in Fig 7) As in the other braces, the short arms pass to the seat of disease, and this makes a very light and effective brace for this region, which is generally considered to be the most difficult to treat mechanically of any part of the spine

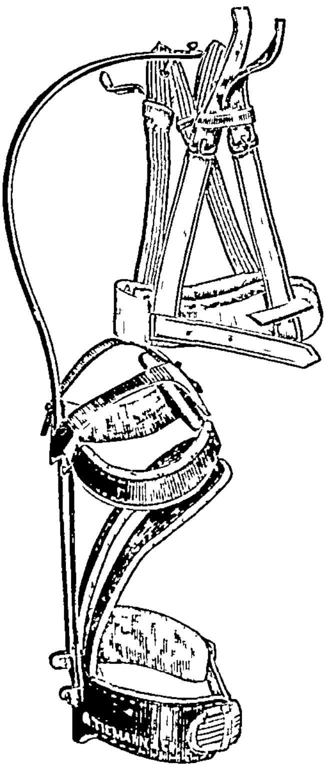

Fig 8 Same with jury mast attachment for cervical disease

For the cervical region or disease of the first and second dorsal vertebræ, the brace just exhibited (Fig 7) should have added to it a jury-mast (as in Fig 8) or a head piece (as in Fig 9), which is provided with facilities for fixing the head firmly in any position, by the insertion in the neck strip connecting the head-piece to the rest of the brace of three clamps, which are so placed as to secure this object The choice between the jury-mast and fixed head-piece in these cervical cases is usually one which the surgeon is called upon to decide for himself, and is to some extent regulated by the gravity of the case, the latter being more effective in caries which is proceeding very rapidly in its course

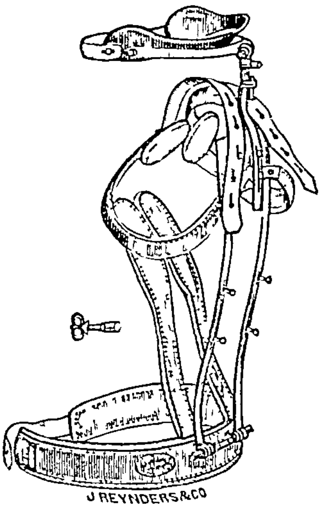

Fig 9 Same, with head piece and clamps in neck strip for fixation in any direction, instead of jury mast.

When the disease is situated in the lumbar, in some cases in the lower dorsal region, and the short arms of the lever are too short to exert sufficient forward pressure upon the kyphos, the lever is reversed, the point of intersection of the long and short arms being placed in the dorsal region instead of over the sacrum In such a brace the base plate is placed in the upper and middle dorsal regions and there secured to the body by appropriate straps From this the short arm lever strips pass down on either side of the spine to the seat of disease where they terminate in pads, the whole being bound down to the body without constriction by a T plate over the sternum (see Fig 12) and the long arm of the lever passes to the sacrum, there terminating in the pelvic girth (see Figs 10 and 11)

When this brace is secured to the body, it forms a V shaped lever which produces extension of the

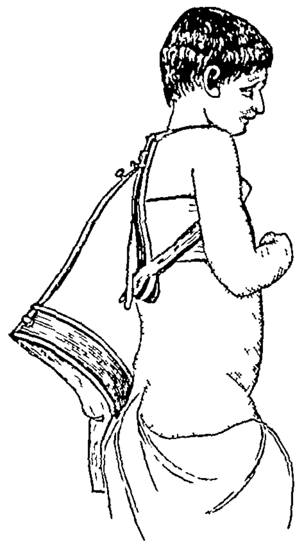

Fig 10 Lever brace for lumbar region with long arm set at an angle with short arm The pelvic girth not yet fastened

bodies of the vertebræ and tends to improve the deformity, while it maintains the spine firmly in the erect position, these being, as we have seen, the desiderata for successful treatment To illustrate this reversal of the lever, so to obtain sufficient leverage to be of use in the lumbar region, a patient is laid on the back upon the padded table, and all that portion of the body *below* the seat of disease is allowed to hang over, just the reversal of the position already demonstrated In this manner also we produce the extension of the spine by means of the backward traction of the lower extremity, and also produce the forward pressure upon the kyphos by the edge of the table It is to sustain these effects when the erect position is assumed that we use the lever brace, and to adapt it to this portion of the spine, we reverse its construction as already detailed

To resume the consideration of the patient before us A brace was constructed for him upon this V lever plan, the apex of the V being placed in the middle dorsal region, and there firmly fixed by a chest-plate and straps so arranged as to secure the base plate to the back without impingement of the soft parts The short arm of the lever passed downward and bifurcated just above the kyphos (see Fig 11), and passing to either side terminated opposite its inferior boundary — In this manner the direct forward pressure of the brace upon the diseased portion, was borne by the transverse processes without pressure upon the kyphos itself

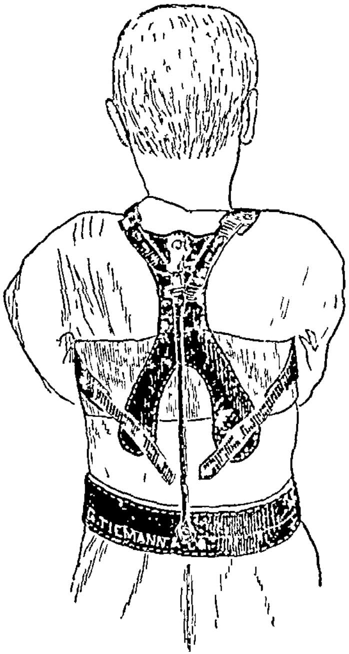

Fig 11 Posterior view of same after pelvic girth is fastened A rotary clamp is shown just below the antero posterior clamp This is used if any lateral rotation of the vertebræ coexists

The long arm passed downward in the median line and terminated in the pelvic band, the clamp at the intersection of the two arms serving to regulate the amount of forward pressure at the seat of disease

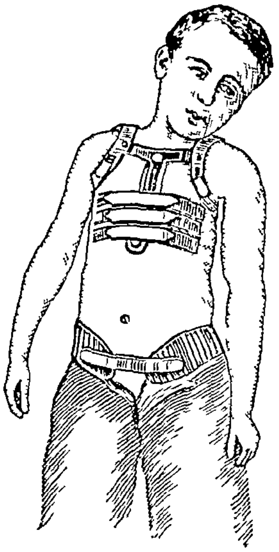

Fig 12 The same anterior view showing T plate and method of strapping

The child is now before you with the brace in position, and as we remove the apparatus and inspect the patient's back, you will see but a slight kyphos, which does not materially increase as he bends forward You will see, as he jumps from the floor at our request, that on alighting, there is no anxious or painful expression upon the face, as there would be if the concussion took place between the vertebræ in an active stage of the disease, and pressure can elicit no points of tenderness

He looks rugged and vigorous, and his stepmother desires to know if he can go without the brace, as he seems to be cured, or, as she expresses it, "just like any other boy," but this we cannot yet advise

We will, however, diminish the forward pressure at the kyphos by decreasing the V angle between the short and long lever, so that the brace will become only a fixation splint of the first class For all practical purposes the disease and its consequent deformity are arrested, and it remains now only to be careful, to restrain the spine for a few months to ensure the improvement becoming permanent, care being taken at the same time, of course, to continue the constitutional measures

There is one more point in respect to the mechanical treatment of these cases which is of prime importance, and that is, the right management

Changes of position during sleep are very apt to cause spinal curves to be assumed which produce compression of the diseased vertebræ, and interfere with the process of repair, and therefore the use of some sort of spinal splint for the night is strongly advised, where the dorsal and lumbar braces already described cannot be tolerated in sleep, and sometimes they can not, although many become so habituated to them as not to have their sleep interfered with, especially if the sleeper lies upon the breast or side A very effective splint may be prepared for night wear by applying a plaster-of-paris jacket during partial suspension

Plaster-of-paris is mentioned first because it is so cheap and procurable, but felt or any other firm, rapidly hardening material will do as well, and this jacket is then to be divided anteriorly and provided with lacings in the ordinary manner So far it does not differ from any other, but the additions which we are about to make to it, to some extent alter its character A pair of thin pads should be placed on either side of the kyphos, posteriorly, and should be attached to the jacket at its edge by strips of metal, which are of a length, equal to the distance from the kyphos to edge of the jacket (P P in Figure

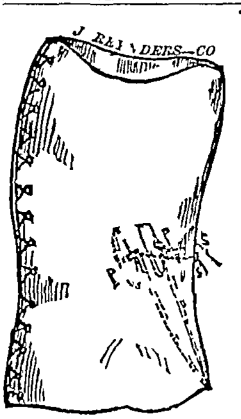

Fig 13 Showing plaster jacket with pads for forward pressure

13) These strips are bent so as to throw the pads inward, and thus become springs to press the transverse processes of the diseased vertebræ forward, when the jacket is applied and laced up, thus producing the effects of the lever brace during the night The forward pressure of the springs may be graduated and controlled by piercing the jacket on either side of the kyphos, and through these passing cords (s s Fig 13) to the pads, so that they may be pulled back against the rear of the jacket, and there secured

This jacket, so modified, is an excellent spinal splint to be used during the day also, since it embodies the principles of the braces just described, and can be recommended for such cases as do not care to use a brace, and also for young children In applying it, draw back the pads and secure them against the back of the jacket by the cords and then when the jacket is laced in front, after being placed on the body, the cords are to be loosened and the pads will then press forward on either side of the kyphos, with a constant elastic force which depends for its intensity upon the strength and angle of the springs by which they are attached to the jacket

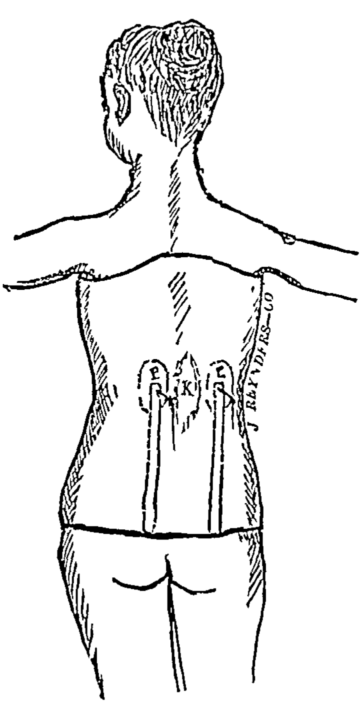

Fig 14 The same applied

(Fig 13 shows such a *lever jacket* with the pads projecting inward and their spring strips attached to the jacket inferiorly, while Fig 14 illustrates the same jacket in position) It is not, however, necessary for the lever or spring effect, that the strip connecting the pads with the jacket should be attached to it inferiorly in all cases, for they may be also attached (although not so advantageously) superiorly, transversely or obliquely, or indeed, in any position so long as the pads are on either side of the kyphos and are forced to exert a forward pressure upon the diseased vertebræ It is perfectly practical also to attach the pads to the back of the jacket opposite the transverse processes of the kyphos, by means of coiled spiral springs, but whatever form of lever or spring is used for its production it is impossible to bring the plaster jacket to its highest degree of effectiveness without the employment of forward pressure at the seat of disease The jacket maintains the body in the erect position, while the pads tend to prevent increase of the deformity and to diminish whatever already exists, until the process of repair and consolidation is complete

---

SPONGE GRAFTING

BY EDWARD C BRIGGS, M D , BOSTON, MASS

Read in Section of Oral and Dental Surgery American Medical Association May 1884

In 1879, Mr D J Hamilton, lecturer on pathology, the School of Medicine, Edinburg, prepared a paper "On the Process of Healing," which appeared in the *Journal of Anatomy and Physiology*, Vol xiii He there made the statement and proved experimentally that in a granulating surface there were no new vessels formed, but that the superficial capillaries of the part were pushed upward, as granulating loops, by the action of the heart, the projection being permitted from the fact that the restraining influence of the skin had been removed

Two years later, in the November number of the *Edinburgh Medical Journal*, Mr Hamilton appears with a communication "On Sponge grafting "

He there states that while getting the information for his former paper, he was led to believe that the process of vascularization, as seen on a granulating surface similar to that which occurs when a blood clot or a fibrinous exudation is replaced by a vascular cicatricial tissue, and that the blood clot or fibrinous lymph acts simply mechanically to give support to the projecting loops of capillaries With this idea he searched around for something artificially to replace the blood clot, and hit upon sponge This, he reasoned, was a porous tissue which would imitate the interstices of the fibrinous net-work of a blood clot Being animal tissue it would, like cat-gut or the blood clot, be absorbed under favorable circumstances I will not go into the details of his experiments, although they would be found very interesting Suffice it to say that his experiments justified his theories

He first experimented with the well known chronic ulcers of the leg A piece of sponge, prepared as I shall describe later, was fitted to the sore, the edges of the sponge being tucked in under the indurated edges of the ulcer Over this some simple antiseptic dressing with bandage

Dressed on the following day the sponge was found partly filled with purulent discharge On dressing the second day, there was *distinct putrefactive odor*, and the sponge was washed with carbolic solution The sponge then appeared slightly red at the most shallow parts, and the edges of the wound reached farther inwards over the sponge

The third day the sponge was beginning to adhere to the granulating surface, and at one point looked as though it were beginning to dissolve The fifth day the thinnest parts of the sponge were growing hard and seemed to be filling with organizing tissue ; picked at these parts it bled freely, showing that the blood-vessels had already begun to climb up through its pores

The growth was slow, but at the end of three months only a small piece of the sponge was to be seen The sponge, when originally fitted to the part, was five inches in diameter

One month later, four months from beginning, Mr Hamilton showed the patient to the Medico-Chirurgical Society, with no traces of the sponge to be seen, and a healthy granulating surface of only an inch and a half diameter

This, the first experiment, was satisfactory in every way, proving the theory correct, and showing that sponge would act even better than blood clot, for while a blood clot would have been destroyed by the putrescent condition of the wound, the more resistant sponge did not seem to be at all affected

Since Mr Hamilton's paper, surgeons all over the world have been experimenting with sponge grafting, and many successful cases have been reported from time to time Seeing these reports, the idea suggested itself to me that morbid conditions in the mouth, associated with loss of the soft tissues, might also be benefited by the use of sponge

In giving my experiments I will state just what I did, and not what I should now do after the experience I have had It happened that a patient of mine, Mr N G B , had been annoyed for three years by a deep depression over the roots of the right superior, first bicuspid, the result of a severe periostitis The chief cause of annoyance was that the food was collected there and the pus retained It was not a simple fistula, but a cavity $\frac{1}{2}$ inch deep and $^{3}/_{16}$ of an inch in diameter I had tried in various ways to restore the lost tissue, or at least to narrow the opening down to a small fistula I had made stimulating applications, had created a fresh blood clot to fill the cavity, hoping it might organize, but all to no purpose ; in fact, the cavity tended to grow larger, until I thought of trying sponge

January 26, 1884, I fitted to the cavity a piece of sponge, previously prepared according to Formula number one of Dr Edward Borck, of St Louis The formula is as follows Take a fine sponge, soak it for three or four days in a 20 per cent solution of hydrochloric acid ; squeeze dry, soak for ten days in a solution of iodoform in ether (ʒi—℥i) ; evaporate ether, and keep in an air tight vessel

Having fitted a piece of sponge thus prepared I dismissed the patient

The next day I saw him, and not expecting any success, I attempted to pull out the sponge To my surprise it resisted my efforts I persisted and pulled it out, disclosing a fresh granulating surface which bleed freely

I packed with fresh sponge The next day I again pulled out the sponge, meeting with the same resistance The appearance was the same as the day before excepting that the space had partially filled up with fresh granulations

This treatment was pursued for two months, after the first week Mr B coming only twice a week The sponge would apparently become attached for a day or two, and then would work out, necessitating the application of fresh sponge I never again got so good an adhesion as after the first piece was put in, and at no time did there seem to be evidence that the sponge would organize ; but, either as a stimulant or a support to the granulations, it accomplished what I had failed to do with other means

The patient now presents simply a small opening admitting a probe about three sixteenths of an inch He is not now annoyed by the collection of food or the retention of pus

As I have said, I had previously tried the blood-clot without success, for, owing to the putrescent condition of the sore, it would always come away in a short time without any change in the cavity being noticeable With the sponge it was different The discharge went on through the sponge, the sponge remaining in position and giving support to the granulations which were not in direct line of the discharge

CASE II About the 1st of April, encouraged by the success of my first experiment, I undertook another case

This patient, Mr J B , relates that three years ago, after a separation had been made between his right superior first and second molars, he began to have trouble in the gum About two years ago, while in Honolulu, the annoyance was so great that he consulted a dentist, who lanced deeply down between the teeth He forced the lancet nearly at the roof of the mouth, and drawing it through between the teeth, to the cheek Where this cut healed the parts contracted, making the trouble worse It did not heal, however, between the teeth, and when I saw the patient, a year ago, there was a deep depression between the teeth The gum bled freely on being touched The annoyance was great, amounting sometimes to severe pain I suggested contouring the teeth to protect the gum, but as the teeth were both very sensitive and the operation would necessitate a great deal of cutting, the patient declined

When, the 1st of April, in response to a note from me, I examined him with a view to trying sponge, I found the trouble worse than ever, the hollow between the teeth at one part extending two-thirds up the roots of the teeth

I began the treatment on the 7th of April After wiping the surface of the gum with deliquesced crystals of carbolic acid, and scraping off the slough, I had a fresh, healthy surface to act upon

I had prepared for this case a sponge in the following manner I first cleaned it of its calcareous salts by washing in dilute aqua regia, then allowed it to remain for twenty-four hours in a dilute solution of tincture of iodine, squeezed it dry and put it in a saturated aqueous solution of boracic acid, ready for use

To protect the gum and prevent the dislodgment of the sponge, I had previously prepared a piece of hard rubber made to arch over the opening between the teeth, resting upon the gum on either side Having fitted a piece of sponge to the exposed surface, I painted the gum and the inside of the rubber cap with a solution of resin, and put the cap in position

In three days I removed the cap, syringed the parts, without removing the sponge, with a 1–200 solution of carbolic acid, and replaced the plate as before

Three days later I again took off the plate, and this time detached the sponge It was only attached on one side, but at that point the gum had already grown down a little On dressing it this time, I returned to the use of sponge prepared as for the first case, having an idea that it worked better I have seen the patient twice a week up to the present time The case is progressing very favorably and the cavity is filling up as rapidly as I could wish

With the present experience I should now, in treating such cases, first be sure that the parts were thoroughly cleaned I should have the sponge shaped as accurately as possible, not forgetting to allow for the swelling , for a day or two I should endeavor to keep some pressure upon the sponge to aid in its attachment After that time, I should disturb the sponge as little as possible, simply washing away the discharge with some antiseptic solution I should wait with patience, not expecting to see great progress in a very short time, and have more faith to believe that if let alone, the sponge would really organize, as in Mr Hamilton's cases

In regard to its application, I think it can be applied not only to such cases as I have described, but to all cases where it is desired to reproduce soft tissues I shall try it, and expect success, in the aggravated cases of the so called "Riggs' Disease," where there is loss of tissue about the roots or teeth

DISCUSSION ON DR BRIGGS' PAPER

Dr Williams —It has been my privilege to see the cases upon which Dr Briggs operated by sponge-grafting, and have noted the marked improvement It is certainly new in its application to the conditions mentioned in the paper, and think its usefulness in this direction will be very great

Dr Ailport —I desire to express my thanks to Dr Briggs for the paper he has read, and I intend to try the sponge-grafting on the first case that presents, in which there is reasonable hope of success

Dr Briggs —I am of the opinion that the sponge-grafting may be successfully used in closing certain cases of cleft palate

OVERDRAFT OF VITAL OR NERVE POWER AS AFFECTING GENERAL AND SPECIAL HEALTH

BY JACOB L WILLIAMS, M D , BOSTON, MASS

Read in Section of Oral and Dental Surgery of American Medical Association May, 1884

The relation of reserve strength or nerve power to the general health, and to the harmonious working of all the functions and faculties, every practitioner has constant occasion to observe To him it is a great source of reliance for continued health, and for permanent remedy of abnormal conditions of organs

The abnormal conditions of different parts of the body have given rise to the various specialties in practice, all, when properly considered, having their relations to the general controlling laws and forces of the system The question may be asked whether, in some departments of special practice, these general laws may not sometimes be too little thought of in all-absorbing attention to local disease?

The relations referred to, it may be proper for the various specialties to elaborate and demonstrate each for itself My present purpose is to make a few suggestions in regard to the influence of reserve nerve force, and the want of it, on some conditions of the oral cavity I say *reserve* nerve strength, for that is what must be drawn on in any contest between health and disease

It is not by a brilliant display of activity, or temporary fortification with artificial tonics alone, that a lasting victory will be gained for health against persistent disease, unless there be within call additional supplies of sustaining and restorative vitality, to meet readily any demands of the case

There is no doubt that a large proportion of people in the artificially active life attending our civilization are maintaining an appearance of fair health while using up all the nerve strength they have every day, leaving practically no reserve, and liable to succumb, as they are constantly doing, at any extra emergency or strain

Indeed, in observing the dental and oral health of individuals, how constantly do we see *persistent* abnormal conditions, which I think can only be accounted for from this fact Such overdraft may be from a constitutional disposition to activity that might be called a nervous diathesis, or from obligatory or voluntary over effort for an object, or from some diseases or conditions of the system drawing greatly on the vital force

Take the very common case of the business or professional man who, from overwork, becomes dyspeptic He is advised to "be careful of his diet," and so forth, which advice he follows punctiliously, still, however, keeping up his usual habits of work, and the dyspepsia is not cured The digestive secretions are not in condition for the healthy and comfortable performance of their office Then rest is directed, and if he takes it in the right way, he becomes better

Now, the idea is not only rational but it seems capable of proof, that not the gastric fluids only, but the secretions of other parts of the digestive system are abnormally affected by the same causes

In such a case as referred to, a greater or less tendency to an unhealthy condition of the oral secretions may be found, which also holding in solution fermentive material, must, as a chemical necessity, sooner or later cause damage to the dental organs

It may be observed that this abnormal state of the oral fluids most commonly follows a continuous rather than temporary over-strain, though I have seen cases of very rapid results from great nerve exhaustion

I would suggest that the condition of the teeth in regard to the degree of their tendency to decay might be one aid, if only as confirmatory, in diagnosis of obscure nervous affections

This relation of cause and effect I have repeatedly seen strikingly illustrated in young persons, who are more readily susceptible in this respect than adults; so that I now commonly expect to find more and greater activity of disease in the mouths of young scholars in the spring and early summer, after a winter season of unremitting application to study and exciting amusements, than in the autumn, on their return from a summer's vacation of leisure and rest There may be no external appearance of variation from standard health, but the greater or less softening of the teeth is very sure to be seen

A case in point, which only represents many actual ones

W M, a lad of 15 years Sept 25th, recently returned in good health from a summer vacation at a quiet seashore place; mouth healthy, teeth sound on approximal surfaces and in the sulci Was advised to come again in four or five months He did not appear till May 18th, following Had been busy and did not like to take the time Said he sometimes felt sensations in eating fruit or sweets On examination I found the teeth, though of normal density looking whiter than last autumn; also found cavities between the superior bicuspids and first molars on both sides, and several cavities in sulci of molars, all of the chalky character indicating rapid acid action To the inquiry, if he had been busy the past winter, he replied that he had been studying very hard to keep a high rank His teeth told the story without the aid of his tongue The same conditions of life were repeated the following summer and the next winter with corresponding results

Another case, of an adult, whose oral health had been exceptional up to forty years of age, being so situated that his ordinary business, requiring no special anxiety, was but an amusement which did not occupy his time very closely; when times changed, and complications and competitions came to engross his constant and sometimes anxious attention

In about a year the teeth began to decay quite rapidly, he complaining sometimes of feeling "nervous," and this condition of oral health has continued, together with his close application to business, for the past eight years The cause and effect seem strikingly evident

A similar condition of the mouth, as well known, very commonly exists during the state of pregnancy, and is often seen when that state might otherwise be called normal The gynæcologist might frequently notice it

A remarkable case occurred under my observation, of a lady of about 44 years, suffering from an ovarian tumor For more than a year she came regularly, at intervals of four or five weeks for observation of the teeth, and there was invariably some new attack of white decay found on them

There is also another pathological condition in the mouth which I have seen to follow or accompany this exhaustion of vital force, viz neuralgic pains at the roots of the teeth, particularly at the roots of the inferior central incisors; though sometimes the pain extends along the line of either jaw, yet with all the teeth having the appearance of health externally, and under the usual tests

When this peculiar neuralgic sensation is complained of, I find on inquiry that there is, or has been, a conscious overdraft of vital force from extraordinary care or anxiety, or excessive effort of some kind Enough cases of this sort to fill another paper might be related, but they would occupy time needlessly, and I will mention but one

Mrs D, about 38 years of age, usually healthy, dental soundness of very good average, after absence of six or eight months called, complaining of thrilling sensations at roots of inferior central incisors; also in upper incisors, and along the line of upper jaw No calculus was found on the inferior incisors, and very little on any of the teeth; no indication of alveolar inflammation; was much exhausted by the little scaling needed She had been anxiously devoted to a sick mother, together with her family supervision, for the past four months

In this relation I have noticed that where the disturbing cause is continuous for some time, the neuralgic condition at the dental roots is apt to be followed by some degree of loosening or unsteadiness of the teeth, even when not accompanied by any accumulation of calculus at the necks, or any evidence of alveolar necrosis That this condition is sometimes mistaken for pyorrhœa alveolaris I have no doubt In such case the heroic treatment sometimes adopted for the latter would be but an aggravation of the malady

The suggestion may properly be made that, although the specialty of oristry has the advantages derived from earnest and accurate chemical and histological investigations, and from increased facilities for acquiring deftness in operative skill, there is yet much room for a more thorough study of the constitutional relations of this department of practice

THE REMOVAL OF STAINS FROM THE TEETH CAUSED BY THE ADMINISTRATION OF MEDICINAL AGENTS AND THE BLEACHING OF PULPLESS TEETH

BY A W HARLAN, M D, CHICAGO, ILL

Read in the Section of Oral and Dental Surgery of the American Medical Association, May, 1884

GENTLEMEN —A large number of remedial agents administered by physicians temporarily stain the teeth but in looking over the list I find there are but few which may be said to permanently stain them The mineral acids—nitric, sulphuric, hydrochloric, and other acids of this nature, if used for any length of time, may discolor the teeth and likewise have a deleterious effect on them; yet it cannot be said that such agents stain the teeth so that any particular method should be desired for restoring their natural appearance The vegetable series may likewise be cap with a solution of resin, and put the cap in position

In three days I removed the cap, syringed the parts, without removing the sponge, with a 1–200 solution of carbolic acid, and replaced the plate as before

Three days later I again took off the plate, and this time detached the sponge It was only attached on one side, but at that point the gum had already grown down a little On dressing it this time, I returned to the use of sponge prepared as for the first case, having an idea that it worked better I have seen the patient twice a week up to the present time The case is progressing very favorably and the cavity is filling up as rapidly as I could wish

With the present experience I should now, in treating such cases, first be sure that the parts were thoroughly cleaned I should have the sponge shaped as accurately as possible, not forgetting to allow for the swelling, for a day or two I should endeavor to keep some pressure upon the sponge to aid in its attachment After that time, I should disturb the sponge as little as possible, simply washing away the discharge with some antiseptic solution I should wait with patience, not expecting to see great progress in a very short time, and have more faith to believe that if let alone, *the sponge would really organize*, as in Mr Hamilton's cases

In regard to its application, I think it can be applied not only to such cases as I have described, but to all cases where it is desired to reproduce soft tissues I shall try it, and expect success, in the aggravated cases of the so-called "Riggs' Disease," where there is loss of tissue about the roots or teeth

DISCUSSION ON DR BRIGGS' PAPER

Dr Williams —It has been my privilege to see the cases upon which Dr Briggs operated by sponge-grafting, and have noted the marked improvement It is certainly new in its application to the conditions mentioned in the paper, and think its usefulness in this direction will be very great

Dr Allport —I desire to express my thanks to Dr Briggs for the paper he has read, and I intend to try the sponge-grafting on the first case that presents, in which there is reasonable hope of success

Dr Briggs —I am of the opinion that the sponge-grafting may be successfully used in closing certain cases of cleft palate

OVERDRAFT OF VITAL OR NERVE POWER AS AFFECTING GENERAL AND SPECIAL HEALTH

BY JACOB L WILLIAMS, M D, BOSTON, MASS

Read in Section of Oral and Dental Surgery of American Medical Association, May, 1884

The relation of reserve strength or nerve power to the general health, and to the harmonious working of all the functions and faculties, every practitioner has constant occasion to observe To him it is a great source of reliance for continued health, and for permanent remedy of abnormal conditions of organs

The abnormal conditions of different parts of the body have given rise to the various specialties in practice, all, when properly considered, having their relations to the general controlling laws and forces of the system The question may be asked whether, in some departments of special practice, these general laws may not sometimes be too little thought of in all-absorbing attention to local disease?

The relations referred to, it may be proper for the various specialties to elaborate and demonstrate each for itself My present purpose is to make a few suggestions in regard to the influence of *reserve nerve* force, and the want of it, on some conditions of the oral cavity I say *reserve* nerve strength, for that is what must be drawn on in any contest between health and disease

It is not by a brilliant display of activity, or temporary fortification with artificial tonics alone, that a lasting victory will be *gained for health against persistent* disease, unless there be within call additional supplies of sustaining and restorative vitality, to meet readily any demands of the case

There is no doubt that a large proportion of people *in the artificially active life attending our civilization* are maintaining an appearance of fair health while using up all the nerve strength they have every day, leaving practically no reserve, and liable to succumb, as they are constantly doing, at any extra emergency or strain

Indeed, in observing the dental and oral health of individuals, how constantly do we see *persistent* abnormal conditions, which I think can only be accounted for from this fact Such overdraft may be from a constitutional disposition to activity that might be called a nervous diathesis, or from obligatory or voluntary over effort for an object, or from some diseases or conditions of the system drawing greatly on the vital force

Take the very common case of the business or professional man who, from overwork, becomes dyspeptic He is advised to "be careful of his diet," and so forth, which advice he follows punctiliously, still, however, keeping up his usual habits of work, and the dyspepsia is not cured The digestive secretions are not in condition for the healthy and comfortable performance of their office Then rest is directed, and if he takes it in the right way, he becomes better

Now, the idea is not only rational but it seems capable of proof, that not the gastric fluids only, but the secretions of other parts of the digestive system are abnormally affected by the same causes

In such a case as referred to, a greater or less tendency to an unhealthy condition of the oral secretions may be found, which also holding in solution fermentive material, must, as a chemical necessity, sooner or later cause damage to the dental organs

It may be observed that this abnormal state of the oral fluids most commonly follows a continuous rather than temporary over strain, though I have seen cases of very rapid results from great nerve exhaustion

I would suggest that the condition of the teeth in regard to the degree of their tendency to decay might be one aid, if only as confirmatory, in diagnosis of obscure nervous affections

This relation of cause and effect I have repeatedly seen strikingly illustrated in young persons, who are more readily susceptible in this respect than adults, so that I now commonly expect to find more and greater activity of disease in the mouths of young scholars in the spring and early summer, after a winter season of unremitting application to study and exciting amusements, than in the autumn, on their return from a summer's vacation of leisure and rest There may be no external appearance of variation from standard health, but the greater or less softening of the teeth is very sure to be seen

The suggestion may properly be made that, although the specialty of oristry has the advantages derived from earnest and accurate chemical and histological investigations, and from increased facilities for acquiring deftness in operative skill, there is yet much room for a more thorough study of the constitutional relations of this department of practice

THE REMOVAL OF STAINS FROM THE TEETH CAUSED BY THE ADMINISTRATION OF MEDICINAL AGENTS AND THE BLEACHING OF PULPLESS TEETH

BY A W HARLAN, M D , CHICAGO, ILL

Read in the Section of Oral and Dental Surgery of the American Medical Association, May, 1884

GENTLEMEN —A large number of remedial agents administered by physicians temporarily stain the teeth but in looking over the list I find there are but few which may be said to permanently stain them The mineral acids—nitric, sulphuric, hydrochloric, and other acids of this nature, if used for any length of time, may discolor the teeth and likewise have a deleterious effect on them, yet it cannot be said that such agents stain the teeth so that any particular method should be desired for restoring their natural appearance The vegetable series may h [illegible] be dismissed The tannates and astringents generally do not permanently stain the teeth The muriated tincture of iron, and in fact all of the ferrum preparations, with the single exception of ferrum dialystum, do stain the teeth, yet it is comparatively easy to remove such stain, by the use of dentifrices and tooth pastes, when of recent occurrence Occasionally it may be necessary to polish the teeth with wooden or leather points charged with finely pulverized emery or levigated pumice, following these, powdered Arkansas stone and precipitated chalk, incorporated with a thick solution of white castile soap, should be used The stains produced by hydrastis, aloes, tobacco, rhubarb, ink, infusion of saffron, pinus canadensis, carmine, catechu, hydriodic acid, tincture of iodine, and kindred agents, are of temporary duration in nearly all cases Not so with tobacco, when the enamel has been fractured, or the masticating surfaces of teeth have been deprived of their enamel by wear In such cases there is no remedy for the stain, when it disfigures, except to cap the teeth with gold This last condition it is seldom found necessary to treat, as in such cases generally it is only imperative when the ends of the teeth have become sensitive to thermal change Staining of the teeth as a result of age, it is not the province of this paper to treat The single substance which I have found to stain the teeth permanently, is nitrate of silver Solutions are frequently used in the mouth and throat of too great strength Many times the powdered nitrate is used to dust diseased mucous membranes, and the teeth then suffer Occasionally, dental surgeons use the solid stick on the walls of sensitive teeth, and also to arrest incipient caries When carelessly used it may stain other teeth than those operated upon These cases are the ones we are called upon to treat It matters not how the stains are acquired, they must be removed, and no amount of polishing, without injury to the external surfaces of the teeth, will remove such stains The agents which may be used for removing such stains are not numerous Cyanide of potassium, iodide of potassium, tincture of iodine, and the liq amm fortior are all recommended There are other substances which may be used to remove fresh stains, notably solution of chloride of sodium, if used immediately I recommend as the neatest, safest, and most certain method, the adjustment of the rubber dam, then dry the teeth, and paint three or four of them with the compound tincture of iodine, allowing it to dry, then moisten the surfaces of the teeth with the stronger liquor ammonia for two or three minutes, and wash the surfaces with peroxide of hydrogen The stains will have disappeared in consequence of the chemical change having taken place resulting in the formation of iodide of silver and nitrate of ammonia The teeth should then be pol

ful

TEETH

t a history of the various
eth in use should be presented
is time, but it is necessary to
them are faulty and very few use-
In order to bleach a pulpless tooth the operator must first fill the root at least one-third its length All decay should be removed and the fragments of the pulp in the fine angles of the outline of the living pulp should also be removed Discolored dentine if hard need not be cut away With the rubber dam adjusted over the adjacent teeth, including the one to be operated upon, the cavity is thoroughly washed with $H_2 O_2$ repeatedly and then carefully dried by using the hot blast from a powerful bulb syringe A small quantity of chloride of alumina is placed within the cavity, and it is moistened with peroxide of hydrogen and allowed to remain five minutes The deliquesced $Al_2 Cl_6$ is carefully washed out of the cavity with a clear solution of sodæ biboras Na 2, $B_4 O_7$ 10 H_2 O, and the cavity thoroughly dessicated In the vast majority of cases the tooth will have returned to its normal color The cause of the change in color is owing to the complete oxidation of the infiltrate into the tubules and the destruction of the staining of the contents of the tubules The tooth should not be bathed in creosote, carbolic acid, alcohol, or any other substance capable of coagulating albumen Where the operator has reason to suspect that any such agent has been introduced into the cavity, it should first be washed with the clear solution of sodæ biboras, and then followed by the above-mentioned method The rapid liberation of chlorine from $Al_2 Cl_6$ in the presence of $H_2 O_2$, resulting in the formation of H Cl and H O, leaving unsatisfied O and Cl accounts for the speedy destruction of the coloring matters within the pulpless tooth In order to maintain the color an oxy-chloride of suitable color should be used to fill the remainder of the pulp canal, and as large a portion of the unfilled cavity as judgment will indicate, thirty to fifty minutes should be given for the hardening of the oxy-chloride The cavity should be filled with gold immediately It is not wise to allow saliva or other liquids to come in contact with the oxy chloride after it is introduced into the tooth It jeopardizes the permanency of every case when oxy-chloride becomes moist, on account of the speedy absorption of fluids by the freshly hardened filling

DISCUSSIONS ON DR HARLAN'S PAPER

Dr Friedrichs —I used to attempt to bleach teeth years ago, but have not made such an effort in the last ten years If our services are engaged in season, there should be no occasion for bleaching, and I very seldom see a case now that requires such service

Dr Harlan —I have tried all the known remedies for discolored teeth, and think from such experience, that peroxide of hydrogen, combined with chloride of aluminium, are the most successful agents It is important, however, that the drugs be good I think Tromsdorff's peroxide of hydrogen and Merck's chloride of aluminium are the most reliable

Dr Friedrichs —In reference to the stains of nitrate of silver (Ag Nt_3), I prefer to remove them by mechanical means, rather than make the attempt by the use of chemicals A stick and pulverized pumice-stone are all that is needed to effectually remove such stains

Dr Brophy —I would ask Dr Friedrichs if he does not find, in some cases, that the stains have penetrated too deeply to be removed by such means?

Dr Friedrichs —I have used this means to a very great extent, and am entirely satisfied with it I have had a great many patients suffering from "erosion," and find that Ag Nt_3 stains do not penetrate beyond the control of such mechanical means as I have mentioned

MEDICAL PROGRESS

MEDICINE.

The Relation Between the Ingestion of Food and Albuminuria —Dr Stanley M Rendall is publishing an article in the *Edinburgh Medical Journal* entitled "Study of a Form of Albuminuria," in the second chapter of which he discusses the relation between the ingestion of food and albuminuria The effect of an albuminous alimentation on the quantity of albumen present in the urine of albuminurics has been noticed for a long time now as increasing the amount of this principle present after meals But all these reports had reference to the existence of augmentation of the quantity of albumen after nitrogenous food, in individuals who were already suffering from persistent albuminuria But within the last year or two attention has been drawn by various writers to the existence of an *intermittent* form of albuminuria in men otherwise apparently healthy In many cases it being discovered merely by acident, owing to a habit of always examining the urine of every patient that might present himself from any cause, however slight, and in many cases its presence being as much a cause of surprise to the medical man as to the patient, until, as in the case of Sir William Gull, its frequent presence in a certain class of cases ceases to excite either astonishment or alarm, and causes the question to be asked, "What worth were mere statistics of albuminuria since it occurred in young men and growing boys almost as frequently as spermatorrhœa?"

The first cases given in detail are those by W Moxon in the Guy's Hospital Reports, 1878, in a paper entitled "On Chronic Intermittent Albuminuria," and a few isolated and undetailed facts have been reported from time to time in the different medical journals Thus, Sir Andrew Clark says "I knew a case in which albumen occurred in the urine daily for several months, but it was only present in the urine passed after breakfast, and was never, to the time of its departure, present at any other time" "Albumen in small quantities, and unaccompanied by casts, may be present in the urine daily for three years, and at last permanently disappear This occurred in a case under my observation The health, which had previously been bad, rapidly improved after the disappearance of the albumen from the urine, and became ultimately very good" Dr Smith, *New York Medical Journal*, 1880, mentions the case of a medical friend who could produce in his own person albuminuria, lasting eight or ten hours, by drinking a pint of milk Claude Bernard, after having eaten several hard-boiled eggs, found his urine albuminous M Marcacci, of Florence, in the *Imparziale*, 1878, after numerous examinations, came to the following conclusions

1 The constant absence of albumen in the urine of the night

2 The very rare absence of albumen in the urine of the day, and then only at the hours furthest removed from the repasts

3 When the albumen was absent it was easy to make it reappear, on indulging in a moderately active exercise sufficient to increase, notably, the number of the pulse

4 The absence of all varieties of tube-casts, epithelial or others

Dr Rendall quotes seven of Moxon's cases, which show that albumen was not found in the urina sanguinis, that is in that excreted during the night, but was in the urina cibi, that is, in the urine excreted during the day Moxon is inclined to believe that this albuminuria is caused by an irritation of the kidneys by morbid matters contained in the urine, such as the oxalates He thinks also that there may be a connection between the appearance of albumen in the urine and the epoch at which the sexual functions complete their development, when their tendencies are not completely under normal control In one of these cases, at least, there was no connection between the vertical position and the albuminuria, for there was no albumen passed either on rising or immediately before going to bed This invalidates the view that it is due to the increase in the weight of the blood column in the vertical position

Dr R Saundby in some notes on the "Diagnostic Value of Albuminuria" found in 145 out-door male patients of the Birmingham General Hospital, taken seriatim, 105 contained albumen, or 72 4 per cent of twenty eight cases under 30 years of age, who were suffering from debility and dyspepsia, and in whom no definite pathological changes could be discovered, ten, or more than half, had albumen in their urine In the other cases, varying from 30 up to 80 years, only one man, who had no definite pathological changes, was found to have albuminous urine In speaking of some of these patients Dr Saundby says "The microscopical examination has revealed usually nothing In one or two cases there were a few oxalates, and in one or two a few hyaline casts, but the latter especially were quite exceptional As for the statement that spermatorrhœa might account for this symptom, it must be remembered that the seminal and prostatic fluids do not contain any albuminous body coagulable by heat

Dr Rendall continues his article by giving in detail three cases of his own, from which may be given the following as the symptoms of post cibal albuminuria No definite complaint, a general malaise existing for months, perhaps, irritability of temper, moodiness, desire for isolation, apathy, fatigue without apparent cause, unrefreshing sleep, failure of appetite and of memory, haggard and drawn appearance, pale and anæmic complexion, no great loss of flesh, no apparent derangement of the organs. In fact, the symptoms as a whole resemble those of oxaluria, there being nothing to draw attention to the urinary system. When it is examined, however, the intermittent presence of albumen is made out. It is always present in well-marked cases after food, its quantity varying with the amount and quality of the aliments taken. On allowing the urine to stand and cool a cloud of mucus is usually deposited, on the top of which the naked eye can frequently make out a thick, silvery line, showing the existence of oxalate of lime crystals; but if the unaided eye fails, the microscope can always detect the presence of this salt. No tube casts, of any kind, can be found in any quantity; but occasionally, after careful searching, one or two crystalline cylinders can be discovered, looking rather like threads of mucus. The reaction is acid, sometimes very much so, and the specific gravity normal. An important negative point, besides the absence of epithelial casts, is the absence of albumen in the water first passed in the morning on rising from bed, and also that passed at any considerable lapse of time after meals if the bladder has been previously emptied of the urine of digestion. Transpiration, far from being diminished, as is the case in true Bright's disease, is increased in some of the cases. In one of those cited, not only exercise but any unusual excitement produced a sensible diaphoresis. Whether all the cases quoted in this paper from different sources can be classed under the heading of post-cibal albuminuria without bringing in another factor than the ingestion of food, is, from the insufficiency of the observations, doubtful. But the majority bear a close relation, and in Dr. Rendall's cases an exclusive relation, to digestion. The explanations given in some of the cases of an "atony of vessels and nerves"; the presence of morbid matters in the urine, such as oxalate of lime, causing an active irritation of the kidneys; a disturbance of the sexual system reflecting a disturbance to the urinary system, or that the albumen is due to the presence of semen, or to differences in the renal circulation produced by the horizontal or vertical position of the body, are all deemed insufficient to explain at least the majority of the cases.

MATERIA MEDICA AND THERAPEUTICS.

ANÆSTHETICS AND THEIR ADMINISTRATION.—Two very interesting and practical papers on this subject have been read recently before the Medical Society of London by Drs. Woodhouse Braine and Geo. Eastes, respectively, and are given in full in the *British Medical Journal*. Dr. Braine considers anæsthetics when they produce a fatal result as practically divided into two classes: 1. Those which produce death in the double manner, through the circulation as well as through the respiration. In this class must be included chloroform, bichloride of methyline, dichloride of ethidene, bromide of ethyl, ethylic methylic ether, and many others of the chlorine series. 2. Nitrous oxide and ether, in which the fatal result, when it does occur, is due to cessation of the respiration only, the heart's action continuing for some time after the respiration has entirely ceased. The three factors one must consider to choose an anæsthetic judiciously, are: 1. The nature of the operation; 2, the amount of insensibility necessary; and 3, the length of time required. The sickness following ether is accompanied, and often caused by, large quantities of flatus; and as it takes place generally very suddenly and forcibly, it is always advisable to stand behind the patient when holding the basin. Chloroform sickness, on the other hand, is preceded by much more faintness and nausea, and takes place more quietly. Hiccough following an anæsthetic is most quickly stopped by the administration of a very small cup of green tea, without milk or sugar, and, should this prove ineffectual, by small doses of dilute hydrocyanic acid. In giving nitrous oxide the room must be kept as quiet as possible during its administration, and no communication should be made to another person, even in a whisper, which it is desirable that a patient should not hear, as at one particular time during its administration the sense of hearing is rendered morbidly acute, all sound being greatly magnified; and this caution holds good also during the recovery of the patient, as the sense of hearing is recovered before that of pain. To get the full effect of nitrous oxide, it must be given pure, all air being rigidly excluded, and if the patient wear a beard, it had better be wetted, or, what is more effective, have a little soap rubbed on it. Deep snoring and an insensitive conjunctiva are good signs of insensibility, but the most trustworthy one of all is subsultus tendinum of the fingers. Pregnant women, even as far advanced as eight months, take nitrous oxide well. Children with chorea, and people who have had hemiplegia, take the gas well. In phthisical patients, if the mischief be extensive, some caution is necessary, as in these cases the anæsthesia deepens after the removal of the face-piece. It is perfectly safe to administer this agent to epileptic patients.

An anæsthetist is often asked by the surgeon, what time in the day will suit him best? "As early in the morning as you can manage it, 8 or 8.30, if possible;" for patients at that hour require less of the anæsthetic to produce insensibility, and their stomachs being naturally empty, they do not experience any of the faintness that is produced by missing a meal. The nervous system of the patient, at this hour of the day, is in its best condition; for there has not been time, since the patient awoke, for the distressing effects of fear and anxiety to have made themselves felt. The patient should not be allowed to become faint from want of food. Should the operation take place before 9.30 A.M. no food of any kind should be given; but if it be the custom of the patient to take a cup of tea or cocoa about 7, this may be allowed; for, having become a habit, it will be missed, and faintness be produced by its omission. If the operation be between 11.30 and 2 let a light breakfast be taken about 8, if that be the patient's regular hour; but if no meal be usually taken till 9.30 or 10 o'clock, then let breakfast be omitted altogether, and a small cup of soup or beef tea be given three hours before the time of operating

The organs of respiration and circulation should always be examined prior to the administration, 1st, to give confidence to the patient and thereby produce a certain increase of cardiac power and a general quieting of the nervous system and, 2d, to enable one to ascertain whether it is advisable to administer the anæsthetic rapidly or not, from the condition of the nervous system The eyes had better be kept open, to reassure the patient by a friendly nod or kind look and give him confidence Artificial teeth, particularly when attached to a small plate, should be removed It is inadvisable to remove a complete upper and lower set, as then the gums come so close together that the flabby lips and cheeks act as a valve and prevent the ingress of air A quid of tobacco may prove troublesome if not looked after Previously to applying the face-piece to the patient's face the anæsthetist should always apply it to his own, to see that everything is in good working order, and that the patient can breathe through it with comfort Dr Braine did this in one instance where a fine spray of bichloride of methylene nearly choked him and made his face smart for a considerable time Within the last two or three months a fatal case has occurred in a London hospital from an ounce of the anæsthetic being injected through the nasal tubes

With a relaxed uvula the patient must be made to sit quite upright, at the same time bending his head forward The uvula in this position swings freely backward and forward with the breathing, but not touching the pharynx it causes no inconvenience Where perfect quiet is required, and mucus about the fauces renders the respiration jerky, by rubbing the forefinger over the back of the tongue and pillars of the fauces the patient is induced to swallow, and thus get rid of the mucus Dr Braine's usual practice is to produce complete insensibility by means of nitrous oxide, and then to quickly change the face piece for the Ormsby or Dublin inhaler(?), so that the irritation produced by the ether lasts but a few seconds, and the patient sinks to sleep without any struggling whatever The cold produced by the rapid evaporation of the ether is often so great that the sponge becomes frozen and gives off but a small quantity of vapor This is best prevented by warming the inhaler before using it, by placing it in a napkin or large sponge wrung out in hot water The most comfortable position for the patient is lying on the side, with one hand and forearm under the pillow, the shoulders being slightly raised and the neck a little bent, so that the saliva, which is always secreted in large quantities, may run from the lower corner of the mouth and not be swallowed This salivary secretion readily takes up ether vapor, and if swallowed is sure to produce vomiting The easiest way to remedy any faintness coming on after the patient's return to bed, is to raise the lower end of the bedstead, supporting it on the end of a sofa or chair, thus making the head and shoulders the lowest part Two minutes and forty-five seconds is rather over than under the average time it should take to produce complete insensibility

Occasionally a patient breathes very slowly, and holds his breath, apparently for a long time, but if by breathing synchronously with him no discomfort is felt, there is no need for anxiety Dyspnœa occasionally occurs from some thick tenacious mucus hanging about the fauces and epiglottis, and this is most easily got rid of by changing the position of the patient's head from one side to the other, or raising the head somewhat, if not relieved, open the mouth wide, by means of the tongue-forceps, and this, producing the act of swallowing (?), may put matters straight If it do not succeed, pull the tongue well out of the mouth, and cause the patient to make a forcible expiration, by sudden firm pressure on his thorax with the left hand and forearm, such a full inspiration will follow that the mucus is either coughed up or swallowed If the patient be anæmic, he must be carefully watched, more especially if the respiration be full and quick, for insensibility then sets in very rapidly, and if it become too deep, great difficulty will be experienced in getting the respiratory muscles to act properly Great care must be taken that the body and extremities of the patient should be kept well covered and warm during the operation, as the anæsthetic generally produces a good deal of cutaneous action

Ether has one very great advantage over those anæsthetics which tend to depress the heart's action, as secondary hæmorrhage is of very rare occurrence In using chloroform we should never remove the inhaler, but pour chloroform onto it while on the patient's face, or, if we do take it away, it must never be replaced within an inch of the face for the first two or three inspirations The pink mottled rash, which appeared in patches over the patient's neck and chest, and was considered as due to chloroform alone, is to be found with every anæsthetic except nitrous oxide Should much pallor be present, or syncope appear imminent, a few whiffs of nitrite of amyl furnish the quickest means of restoring the heart's action The anæsthetist's bag should always contain a pair of tongue-forceps, a Fergusson's gag, a scalpel, forceps, and tracheotomy tube, and a few capsules of nitrite of amyl After the operation no food of any kind for three hours, and after that not until asked for All nutriment used to be cold until next morning Avoid milk, give beef tea, jelly, and such fruit as grapes and oranges

Dr Eastes' remarks were mainly confirmatory of those of Dr Braine

THE TREATMENT OF RINGWORM —Alder Smith, M B (*British Medical Journal*), gives the following I desire now to call attention to a treatment for recent ringworm, where it does not extend over any large extent of surface It is not a new remedy by any means, but, I believe, a new way of naming a well-known parasiticide I have been trying for some time to find out what vehicle penetrates most deeply in the hair follicles, and think it is chloroform Chrysophanic acid is a very good parasiticide and, though it is insoluble in spirit and ether, yet it is soluble in chloroform Chloroform also dissolves the fatty matter out of the hair follicles, and thus allows the parasiticide dissolved in it to penetrate deeply During the last year I have used a solution of seven grains of the acid to the ounce of chloroform to all cases of recent ringworm, and believe it is the most efficient treatment I have yet tried The small patches should be carefully marked out by cutting the hair very closely on them, and the chloroform solution should be well pressed and dabbed into the places with a minute sponge-mop for five minutes, two or three times a day, according to the amount of irritation produced The aim of the treatment is not to produce scabs, but to get the solution to penetrate deeply The sponge-mop should not be much larger than a big pea, and should be continually dipped into the chloroform bottle, as the solution soon evaporates whilst it is pressed into the diseased spot, and leaves the yellow acid dry on the place Great care must be taken that the solution does not run onto the forehead or into the eyes, and that the person using it does not inhale the vapor I always give full directions about the care necessary in using such a potent remedy, and only employ it to weak places of the disease It is well for the nurse to keep her face away from the sponge, and to use the chloroform in a current of air, and not in a small room The places should be well washed every morning with hot water and soap, to remove any sebaceous matter or crusts, and the hair should be kept closely cut on them till the new hair appears, which is generally in about two or three months, but the remedy should be continued till all the diseased stumps have come out

GONORRHŒA INSONTIUM (BLENNORRHAGIA OF CHILDREN, INDEPENDENT OF SEXUAL CONTACT) —The *Lyon Medical* gives an interesting résume of this subject Prof de Amicis has noticed in children the presence of a spontaneous vulvo-vaginitis with a specific coccus, he believes that the coccus of Neisser can be found in the products of catarrhal inflammations without sexual contact

Dr Kroner has found the gonococcus in two-thirds of the cases of ophthalmia blennorrhœa in new-born children that have been submitted to his examination

Tischendorf has seen in the hospital of Hamburg, children suffering from scarlatina or wearing extension apparatus, *acquire* vaginal blennorrhagia where the gonococcus of Neisser was present without any other affection being present This would seem to show the existence of a spontaneous blennorrhagia in which the presence of the gonococcus went for nothing, being simply a common organism, which might be found in all mucous inflammations

The partisans of the specific doctrine consider that the child contracts the blennorrhagic vulvitis by infection, either during or after birth The reason why there is infinitely less of vulvitis than of ophthalmia, is because all children without distinction of sex are exposed to ophthalmia by the absolute frequency of head presentations, while the girls in the very rare proportion of breech presentations (3–100), are exposed to blennorrhagic vulvitis, the length of the urethra, protected by a long prepuce being the safe guard for boys After birth the chances are equal for the vagina and for the eyes, if a contaminated mother washes the genital organs of a child with the same linen or sponge that she has used for herself In Cazenave's Annales a case is reported where a mother affected with blennorrhagia, took her two girls, aged 4 and 8 years, into the bath with her and communicated the affection to both of them

It seems probable that the gonococcus is the sign of a contagion, independent of sexual contact, but dependent in great part to the contact of the bed, the bath, linen, sponges, and perhaps also the dropping of infected urine outside of the vessel intended to receive it under various circumstances Erosions also, as from scarlatina, or produced by the contact of apparatus, would facilitate the contagion It is difficult at this stage of the question, to admit a spontaneous blennorrhagia, but a greater and greater reserve should be held in the medico legal decision of a blennorrhagia attributed to criminal acts, which might arise from accidental causes

TREATMENT OF THE SOFT CHANCRE BY IODOFORM — Unna finds (*Monatshefte fur praktische Dermatologie Edin Med Jour*)that for the present no remedy heals the soft chancre more rapidly than iodoform, and none with such certainty obviates the occurrence of a suppurating bubo The drawback is the peculiar and suggestive odor, which no combination serves entirely or permanently to mask One cause of the diffusion of the odor is the custom of employing iodoform in powder too much, more than necessary is thus applied, and the powder is apt to be deposited on the clothes during or after application He therefore advises that iodoform dissolved in ether be used The sore is first dried with absorbent cotton, then a drop of the iodoform ether allowed to fall on the sore, and the evaporation of the ether fanned by blowing on it with a hand-ball bellows Thus a thin coating of iodoform is deposited exactly on the ulcer Over the ulcer so coated, he places a small piece of perforated iodoform plaster muslin, which has been brought to perfection as regards its preparation by Beiersdorf, Altona If this appears too thin, a circular band of the same can be wound round the penis, or a strip applied if the ulcer is seated elsewhere Lastly, to conceal the smell, a piece of cotton wool, perfumed by means of a spirituous solution of curnaim, is placed over all If desirable, this wool can be sprayed over with some volatile aromatic fluid When the ulcer occurs in the meatus urinarius, he supplies the patient with a pencil of iodoform composed as follows

℞ Iodoformi .	10 0	
Gummi Arabici	3 0	
Gummi Tragacanthæ	1 0	
Glycerini	1 0	
Aq	q s	Misci fiat bacilli, N 5

These are kept in a little wooden box After voiding urine, the pencil, made pointed, is dipped in water and several times introduced with a screwing motion into the meatus A small piece of the perfumed wool is now passed in between the lips, and a larger piece wrapper round the glans Unna further remarks that these pencils serve as valuable prophylactics against infection from gonorrhœa or soft sore.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 65 RANDOLPH STREET,
CHICAGO ILLINOIS

SATURDAY, JANUARY 31, 1885

OVARIOTOMY STATISTICS —Our readers will remember that in the JOURNAL of Oct 25, 1884, we published a brief letter from Prof Donald Maclean, correcting a simple error in the date of an ovariotomy alluded to by him in a debate in the Section of Obstetrics and Diseases of Women of the American Medical Association, at the last annual meeting, which was followed in the JOURNAL of Nov 15, by a note from Dr R S Sutton, saying that he had a "Death Certificate" of another case, and asking if Prof Maclean would add this to his previous correction To this the latter replied in the JOURNAL of Nov 29, declaring that if such certificate existed, it was either a gross blunder or a forgery To offset this, Dr Sutton promptly forwarded to us the certificate he held, asking for its early publication It was in the usual form of death certificates used in cities where such are required by law, and on its face gave the cause of death as "*Ovariotomy*" But careful examination showed that it was not signed either by the attending physician of the deceased or the operating surgeon And further information showed that the signer of the certificate had done it to accommodate the undertaker, and had given the cause of death as a "Surgical Operation" without assuming to know or state what kind of operation it was Afterwards some other party, whom we have not been able to identify, crossed out the words "Surgical Operation," and inserted the word "Ovariotomy" without the knowledge of the signer of the certificate In that condition it appears to have been sent to Dr Sutton Of course, *such* a certificate is utterly worthless, except as an example of how carelessly many death certificates are filled, and we refused to publish it

From several sources, including Prof Maclean himself, we learn that the death to which the certificate referred, was that of a lady who had suffered many years, and until near the stage of fatal exhaustion, not from ovarian cysts on tumors, but from such symptoms as are supposed to be sometimes relieved by Battey's operation or technically Oophorectomy, which operation was performed just before the patient died

When we published, a few weeks since, in this JOURNAL, the case of Successful Ovariotomy, by Dr Geo E Ranney, of Lansing, Mich , we had no knowledge of the fact, that the same case had already been reported by Dr E W Jenks, of Detroit, and published in the *Medical Age* of that city The number of the *Age* containing it had escaped our observation Having published the case as reported by Dr Ranney, we could not properly refuse to publish the letters of both Drs Jenks and Ranney, in which each gives his own exposition of facts and circumstances in full, by which we think every attentive reader will infer that as the two gentlemen had mutually participated in the performance of an important surgical operation, they should have equally cooperated in reporting it for publication Having given both parties a full hearing, we do not feel at liberty to encumber our pages with any further personal controversy on the subject

CORRECTIONS In the list of *Permanent Members* of the American Medical Association, published in the JOURNAL for December 27, 1884, the name of W J Herdman, of Ann Arbor, Mich , is incorrectly given as W J Heronnan —The residence of A H Steen, of Cottage Grove, Minnesota, is incorrectly placed in Wisconsin, and I P Klingensmith, of Blairsville, Pa , is wrongly placed at Derry Station, Pennsylvania

In the JOURNAL for January 10, 1885, is a brief paper on the Treatment of Diphtheria, by Dr J W Brown, of New York, which was discussed by many of the members of the Section of Diseases of Children at the recent meeting of the American Medical Association As the report of the secretary of that Section appeared to have been prepared with more care than usual, we ventured to append his notes of the discussion to the paper as published But Dr S C Busey, of Washington, D C , writes us that the remarks attributed to him on page 32 are so far incorrect that he would not recognize them as representing anything he had said

INSTABILITY OF MEDICAL INTERESTS DEPENDENT ON MUNICIPAL OR COUNTY POLITICS —The Cook County Hospital, which is the legal receptacle for the sick poor of Chicago and Cook Co , is under the direct control and management of the Board of County Commissioners, a certain proportion of whom are elected annually

The Board appears to have adopted the rule of electing the members of the medical and surgical staff of the Hospital at the commencement of each year, and of allowing each Commissioner to name one member of the staff While this affords an admirable opportunity for each Commissioner to reward, with an appointment, either his own family physician or such other medical man as may have rendered him most aid in securing his own election, it destroys entirely the stability of the medical staff of the Hospital, and greatly impairs its usefulness for clinical instruction At a recent meeting of the Board of Commissioners, when each Commissioner had named his member of the Hospital Staff, aggregating fourteen, it was found that five of the most active and efficient members of the old staff had been dropped

To obviate this, the Board immediately voted to enlarge the Staff, and elected the *five* as " members at large " At the same sitting eight so called Homœopaths were elected to attend the hospital wards, set apart for their service, thus giving to the Cook County Hospital a Medical and Surgical Staff of twenty-seven doctors of "all sorts "

Numerically, this should certainly be sufficient to prevent any suffering on the part of the poor patients, for lack of professional attendance As if to still further demonstrate the unreliability of anything medical under the control of the County Board, the Central Free Dispensary, which had hitherto been accommodated in the basement of the Rush Medical College, and made useful for clinical instruction, was ordered to be removed to rooms in the College of Physicians and Surgeons, with a good prospect of continuing an annual migration until it has had a brief residence in each of the four medical colleges surrounding the County Hospital square

We allude to these local affairs simply to illustrate the general proposition that no medical college in this country can rely upon any public hospital under municipal, *i e*, political, control for its important department of clinical instruction, and as a consequence, every medical college to ensure permanence, and a high degree of usefulness, must have an adequate general hospital, substantially under the control of its own faculty of instruction Time and experience has compelled both the old and leading medical schools in Philadelphia to erect their own hospitals Progress is being made in the same direction in New York and other cities The Chicago Medical College in this city has from its beginning to the present, had its own ample hospital clinical advantages, wholly independent of municipal or political influence, and the Rush Medical College, which was the first to attach itself to the County Hospital and follow it to its present location, has already practically acknowledged its mistake by procuring the erection and opening of the new Presbyterian Hospital on its own grounds

We claim that a public general hospital located in the midst of a population sufficient to keep, at least, 75 to 100 beds filled with patients, should be regarded as much an essential part of a medical school worthy of patronage, as an anatomical, histological, or chemical laboratory And the advanced students should be divided into suitable classes for systematic personal clinical instruction in the Hospital and dispensary wards, as thoroughly as the Juniors are in the laboratories just named

SOCIETY PROCEEDINGS

REMOVAL OF UTERUS AND OVARIES BY ABDOMINAL SECTION, FOR FIBRO-MYOMATA DEATH ON TWELFTH DAY, FROM SEPTICÆMIA.

BY J M BARTON, M D , PHILADELPHIA, PA

Read before the Philadelphia County Medical Society, December 17 1884.

Mrs K , æt 31 years, was brought to me, last September, by Dr M B Dwight, of Jersey Shore, Pa She was very pale, the face and lips being entirely colorless , indeed, the appearance of the patient suggested the presence of malignant disease She had to be carried to her room on her arrival in this city She had been losing more blood than she should for several years, and for several months she had a daily loss, frequently in quite large amounts, and was losing strength rapidly

On examination a large, hard, smooth and freely movable tumor, evidently the uterus, extending three inches above the umbilicus, was found , by the sound, Dr Dwight's diagnosis of a sub mucous fibroid with extensive uterine attachments, was readily confirmed

As the uterus was entirely out of the pelvis, as the attachments of the tumor occupied more than three-fourths of its entire circumference, and as the remaining uterine wall was much thinned, removal by the vagina was plainly impossible I advised extirpation of the ovaries, if accessible, or of the entire uterus if, on exploration, it appeared preferable

The patient returned to her home, as she preferred to have the operation performed there, to which I agreed, as I considered the mountain air much more favorable for operation and after-treatment than the wards of a general hospital

On September 30 I visited Jersey Shore and removed the growth, assisted by Drs Dwight and Cline, of that place, Drs Detweiler and Youngman, of Williamsport, Dr Armstrong, of Lockhaven, and Dr Orville Horwitz, of Philadelphia

Thorough antiseptic precautions were taken, the hands of the operator and assistants were washed in carbolic-acid solution, all the instruments and ligatures were immersed in a similar mixture, the sponges were washed in a warm solution of the same acid, the abdomen of the patient was washed first with turpentine, then with soap and water, and lastly with carbolic acid solution

I made an incision through the abdominal wall, midway between the umbilicus and pubes, about two and a half inches long, through which I readily drew the right ovary, the left, however, could not be reached Finding the uterus free from adhesions, and movable, we decided to remove it I increased the incision until it ran nearly from ensiform cartilage to pubes, carefully checking all hæmorrhage by forceps and catgut ligatures before opening the peritoneum, the uterus was readily lifted from its bed and placed upright, the left broad ligament was attached posteriorly and the left ovary laid against the spine, showing that it could not have been reached through the original incision The intestines were held away from the uterus and supported by large flat sponges, wrung out of warm carbolic acid solution The broad ligaments were tied in sections with carbolized silk and Thomas's large clamp placed upon the neck of the uterus

Surrounding the parts with sponges, to prevent blood entering the peritoneal cavity, into which so far none had escaped, the uterus and both ovaries were rapidly removed, there being but little tension on the pedicle, we decided to treat it outside

The stump was trimmed so as to leave but little projecting above the clamp, it was transfixed by a large pin and was seared on its cut surface by the actual cautery, the wound was closed by the interrupted suture introduced from within in the usual manner It was not found necessary to make the "toilette of the peritoneum," as, thanks to the care of my assistants, no blood had been allowed to enter that cavity, and, indeed, but little was lost during the entire operation

The uterus was seven inches in diameter and nearly a sphere, it was occupied by a single fibromyoma, which was attached to the entire uterine walls, with the exception of a narrow channel about two inches wide, running from neck to fundus, on section, it presented the usual appearance of such growths, except in its centre, where it appeared to have undergone sarcomatous degeneration, this suspicion was subsequently confirmed on microscopical examination

The after treatment of the case was in the hands of Dr Dwight, from whose very complete notes I take the following points —

The evening of the operation the temperature rose to 102 5°, the pulse to 120, under opium suppositories and occasional hypodermics of morphia, the patient was quite comfortable, she took nothing whatever into the stomach, except small quantities of hot water, and had no vomiting On the second day the thermometer rose to 104°, the maximum temperature observed

On the third day she took some barley water and in the evening some beef-tea, the general condition being improved and improving still more on the fourth day

On the fifth day (Oct 4) the bowels were moved by an enema, opium stopped, beef-tea, brandy and warm milk were taken freely, the patient was quite comfortable

On the sixth day (Oct 5), patient rested well during the night, takes warm milk every three hours, pulse stronger, 120, temperature 101°, patient looks quite bright, natural movement of the bowels

The notes of the seventh, eighth and ninth days are almost identical with the last one read, except that stitches were removed, and on the ninth day there is considerable pus coming from wound, and some swelling of the right parotid gland On the tenth day the swelling of the parotid gland increased, there were evidences of systemic poisoning, and on the evening of the eleventh day she died

At the autopsy, there was no inflammation of intestine, there was no pus found in lungs, liver or kidneys, though there was some in the abdominal cavity—this had probably entered a day or two before her death, and from it the blood-poisoning, which proved fatal, arose

CHICAGO MEDICAL SOCIETY.

A regular stated meeting of the Society was held January 3, 1885

Upon motion, duly seconded, the reading of scientific papers was temporarily deferred, and the following preamble and resolutions were submitted by the Secretary in behalf of the Memorial Committee, upon the death of Dr Chaffee In doing so, the speaker stated that but a few months previously the deceased called upon him, and during the conversation said how well to do he was, and that he hoped soon to be able to take a vacation His auditor was *rather* impressed at the time that what was intended in those remarks, as much as any other, was "the uncertainty of life" Dr Chaffee was elected a delegate to the American Medical Association last year, but professional duties rendered him unable to accept the proffered honor

WHEREAS, It has pleased the Ruler of the Universe to arrest the course of our friend and neighbor, Dr C W Chaffee, while he was yet in the prime of healthful vigor and usefulness, and actively engaged in discharging, as usual, the daily duties of his calling—

Resolved, That in the death of Dr Chaffee, this Society has lost a conscientious and successful practitioner, and a colleague in whose keeping the reputation and interests of any professional brother were safe from harm

Resolved, That the community has lost a genial companion, a faithful servant, a useful and upright citizen, and the sick poor have lost a ready benefactor

Resolved, That this Society extend to the bereaved family and friends assurances of sincere sympathy

Resolved, That these resolutions be incorporated in the records of the Society, and that a copy be forwarded for publication to each of the daily papers of the city and to the Journal of the American Medical Association, and that a suitably engrossed copy be transmitted to the family of the deceased

Committee

"Diphtheria, with Remarks on the Germ Theory, and Treatment of Cases with Alcohol," by Dr G H Chapman, was the lengthy title of the first paper read, which was also extensive, yet the writer did not enter minutely into this subject, but simply gave a few facts which have in his experience proven of value in combating this disease, of which the following extracts have been taken

And first, as to its development Is it local in character, or does it involve the whole system? Both theories have their advocates Perhaps the most recent and well-founded theory is that given by Oertel, and confirmed by others, "that the disease is first local, and afterward develops into a general disease, and moreover, that the infection is kept up by the local disease The micrococci first attach themselves to the pharyngeal mucous membrane, where they multiply and produce inflammation of the adjacent tissues, and the membrane becomes filled with micrococci, which force their way between the epithelial cells The cells begin to die and ulceration takes place, the mouths of the lymphatics open, and the micrococci pass in Early in the disease no micrococci are found in the blood, but after the constitutional symptoms have become severe, masses of them will be found in the vessels, and the germ invades the white blood corpuscles, which after a time will be found filled with micrococci, they will be found in the kidneys, and in the capillaries, forcing their way between the muscular fibres of the heart, and throughout the body, leading to destruction of tissue

"Drs Wood and Formad, of Philadelphia, during their experiments found that when the attempt was made to inoculate animals with the poison derived from an ordinary case of diphtheria, as it appeared in that city, it failed to produce the disease, but when taken from those who were subjects of malignant diphtheria it invariably succeeded in infecting the lower animals They also produced diphtheria with micrococci when cultivated in soups, even to the fourth or fifth generation They further found in ordinary saliva a micrococcus which cannot be distinguished from that found in the membrane from the most malignant case of diphtheria, except that those of the former would not produce the disease, and also that the severity of the poison was directly as infectious as the virulence of the epidemic from which the poison was taken The former gentleman thinks that diphtheria is produced by micrococci that are present in everybody's mouth" These are the conclusions of those who have spent years in the investigation of this subject, with abundance of material at their disposal

If, as they affirm, "micrococci can be found in ordinary saliva which in no way differs from those found in the malignant diphtheritic membrane," except possibly that they are inert, even though found only in the saliva of those who frequent or inhabit an infected district, it would seem to prove that they alone are not responsible for the development of diphtheria There must be conditions for their rapid reproduction which are not yet understood, and may it not be, that these micrococci find in this degenerated or septic condition of the fluids and tissues a good field for growth and development in an active form, and still not be the primary cause of diphtheria?

Be the disease, however, purely local or general in its origin, be there micrococci or no micrococci as a primary cause of its development, the stubborn fact remains that in nine cases out of ten, when the physician is first summoned to attend a case of diphtheria, he finds abundant evidence of general systemic disturbance, varying in degrees of intensity from simple circulatory excitement to the most profound degree of prostration, the same as that which is found in septæmia, and as such we are obliged to treat it

A severe form of this disease manifested itself in South Chicago during the fall and winter of 1881 and 1882 In the first six weeks of the epidemic the writer treated seven cases, with two deaths and one protracted recovery out of three malignant cases The treatment in these cases was, externally, the free use of camphorated oil with turpentine, and applying to the membrane every five or six hours, with a camel's-hair brush, the following

℞	Acid carbolic	ʒi
	Liq ferri sub sulph	ʒiii
	Glycerine	ʒiv
M		

and during the intervals, he directed frequent gargling the throat with a saturated aqueous solution of chlorate of potash Internally, there was administered tr ferri hydrochlor, and quinine in doses suitable to the age of the patient, giving to a child eight years of age, two grains of quinine and six drops of tr iron every three hours In the case which seemed malignant and recovered, dry sulphur was used after the fourth day, blown freely into the throat and nasal cavities after cleansing with the chlorate of potash solution

There had been up to this time about twenty cases in the immediate vicinity, with twelve deaths, other physicians, foreign and local, having no better success in combating the disease than the writer At this time his attention was called to the free use of alcohol in this disease in an article published in the Boston *Journal of Chemistry*, and another article published in the *Eclectic Medical Journal*, of Cincinnati, also to the details of experiments on diphtheritic membrane in Ziemssen's Cyclopædia, Vol 1, p 680, from which it was inferred that alcohol was one of, if not the best, agent to destroy or render inert the micrococci, and he determined to give alcohol a fair trial, and use this remedy diluted with chlorate of potash, as a gargle, every half-hour, always washing the mouth with the solution of potash before the patient took either medicine, food or drink Dry sulphur in the throat and nasal cavities was also used, with the internal use of whiskey sling or milk punch as hot and strong as could be borne, and only to be limited by the amount which could be tolerated by the patient without producing intoxication, along with other agents, as diuretics, anti-febrile remedies, etc , etc , as each case seemed to demand

As a result of this trial the writer reported that his succeeding twenty-eight cases were carried to a successful termination, with one exception, and in none of them was a brush or probang used to the throat

The alcohol, in every case, could be used very strong, and it would almost invariably cause the membrane to shrivel up like burning leather, and within thirty-six to forty hours from time of commencement of treatment every trace of membrane disappeared Tr Verat Viride et Tr Opii Deod were given in some cases for fever during the congestive stage only

During the past two years Dr Chapman has relied on the liquor ferri sub sulph and carbolic acid mixture, applied to the throat with a camel's hair brush twice or thrice a day, or still more frequently This plan he pursued instead of blowing in sulphur with a bellows or through a goose quill The sheet anchor, however, is alcohol in every stage of the disease, and from his experience in using it he is led to think we can secure much better results from this remedy than to rely on the harsher methods of treatment

DISCUSSION

Dr G C Paoli thought the author of the paper was too prone to follow out routine treatment in diphtheria, whereas no such form can be laid down in the treatment of this disease Malignant cases may live only two, three, or at most five days, and this is not the fault of the physician However, alcohol is no new remedy in treating these cases It has been used for years, mostly, though, in the form of wine Alcohol may be given in these cases to destroy fungi or bacilli, on the same theory that it is given as an antidote for snake-bites in those who have been bitten by poisonous reptiles But the question arises will alcohol save cases where there is a fibrous exudation of the tonsils, pharynx and other organs, where it is of an ashy gray appearance, where the maxillary and cervical glands are involved, where a patient has a dusky hue of the face with cyanotic lips, feeble heart and feeble pulse, fœtid breath, hyperæmia of the brain, etc? He should hesitate about giving the remedy, on general principles But instead, the first thing that should be done is to use antiseptics, as oil of eucalyptus, which will destroy the bacilli For young children we should use it with an atomizer, for they cannot gargle their throat Where there is ulceration of the nasopharyngeal space, hæmorrhage may set in, if so, nothing will check it Internally we should give tr iodine in water, say four drops every hour to a child five years of age, and apply with a probe or brush to the throat any of the well known antiseptics It is no use to give them quinine and tr iron, for these remedies they cannot take, and besides they interfere with the secretion of the kidneys and liver He would like to speak upon some of the sequelæ of diphtheria, as paralysis of the larynx, septic poisoning, spinal difficulties, etc , but he believed the paper did not dwell upon these

Dr R Tilley desired to add his testimony to the special value of tr iodine in these cases, although no one individual remedy can be used in all of them He also thought corrosive sublimate was beneficial, and he placed great reliance upon it But he preferred the use of hot baths in the early stage of this disease as being beneficial to facilitate profuse perspiration instead of using tr veratrum viride No one disbelieves but what bacteria is a causative agent of this disease He is satisfied that this is true

Dr J J M Angear —The "microscopist" has settled it, that micro organisms or microbes are a cause of diphtheria Alcohol, as is well known, destroys vegetable growths A fifteen per cent solution of alcohol prostrates or paralyzes them, and if the remedy is continued it would kill them He therefore thought it a good local application But these germs flourish best in a high temperature We cannot get alcohol as strong as a fifteen per cent solution to circulate in the blood Therefore how does it kill them when the blood contains them? Then, too, why the utility of administering alcohol and veratrum? Do not these remedies antagonize each other? There is harmony between the germ theory and the local use of alcohol But he would think cold applications were preferable to hot drinks, or preferable to hot baths, for the reason that germs flourish better under a high temperature

Dr A Leigh —In an experience of treating between 100 and 120 cases of diphtheria during the past four years, stated that of all agents *per se, hot or cold,* there was none better than a concentrated or dilute preparation of the perchloride of iron , but where a case is truly malignant, and where there is purpura hæmorrhagica, no treatment will save them Alcohol, hot or cold, is a good cardiac stimulant, but quinine will do the work better A tincture of the preparation of iron just alluded to would produce contraction or hardening and shriveling of the membrane There is no possible doubt but what micrococci are present in the throat in this disease Therefore, if these cases are seen early, and if the iron is applied, a benefit will be derived, except where the case is profoundly malignant He thinks tincture of aconite is superior to veratrum to bring about free diaphoresis

Dr H J Reynolds had come to the conclusion that there were no remedies that had a specific effect on diphtheria, whether it was of germ origin or not, the most that could be done was to rely upon supporting measures to help the patient along until the disease subsided If the membrane enters the larynx, he advises inhalation of steam He thought no benefit would be derived from alcohol or veratrum. Where the disease is malignant at the onset, as he had seen cases, with a pulse of 190 per minute, no treatment was beneficial

Dr W H Curtis inquired of the last speaker how he managed to count the pulse when it arose to 190 per minute?

Answered meekly and politely, "By the watch"

Dr A Goldspoon said that he had treated one hundred cases of diphtheria during the past two years He alluded to the constitutional disturbance as not being solely due to the amount of local invasion in all cases He had seen great constitutional disturbance present when the local signs were quite insignificant, and cited a case of this kind occurring to a little girl who died in ten hours from the time she was attacked The system was so depressed that she died of heart failure In such cases it would be reprehensible to administer aconite or veratrum To reduce the temperature he relies upon quinine Alcohol cannot be given sufficiently concentrated to act throughout the circulation as a germicide, constitutionally It may do good as a local agent, but the former idea, he thinks, is surely inconsistent

Dr Paoli—It is a historical fact that diphtheria appears in countries and at a season when the temperature is very low, and the disease is equally as destructive Alcohol may prove beneficial in some cases that are peculiarly asthenic

The President recited an epitome of Morrill McKenzie's views upon the pathology and treatment of diphtheria, and Dr Chapman closed the discussion by stating that it was difficult, and even impossible, to produce intoxication in a patient having diphtheria He claimed that by treating cases this way paralyses were less liable to follow He is sure it also quiets the cerebral symptoms, such as delirium, and does not increase hyperæmia of the brain Regarding the administration of veratrum and alcohol alternately, he does this during the first, or congestive stage, or until perspiration is well established His experience and success with this treatment have been far better than brother physicians of his neighborhood had been who did not treat their cases similarly He certainly would continue to do so, even if it did appear to be in discord To continue giving alcohol, in the form of whisky, we should commence early, and by so doing the fungi are destroyed, and we prevent their entering the blood vessels by using the remedy freely and constantly, or if a few do enter the circulation it was not so bad as if they passed in in swarms

The following is an abstract of an article on "Manganese as a Remedy in Menstrual Troubles," by Dr Franklin H Martin

Manganese was first recommended as a remedy for amenorrhœa, in an article published Jan 6, 1883, in the *London Lancet*, by Ringer and Murrell After a goodly number of experiments upon dispensary and private patients the results of the writer's investigations were published in the *New York Medical Record*, September 29, 1883 That report elicited considerable correspondence, giving the results of the investigations of others Dr Martin has continued his experiments with considerable zeal, ever since, and he thinks he is able to add much confirmatory evidence to what has already been said He is convinced that manganese will relieve certain forms of menorrhagia and metrorrhagia, as well as amenorrhœa As these several conditions are dependent upon so many different causes, it is very necessary for us to discriminately point out the exact conditions in which manganese is indicated

From his observations, he is led to consider manganese in *any form a direct stimulant to the uterus and its appendages* Its influence may be exerted by acting as a direct vaso motor nerve stimulant to the vascular system of these organs, and in consequence of improved circulation it directly increases the tone and nutrition of the organs, or it may exert its whole force through stimulation of the sexual nerve ganglia, or even, possibly, the *sexual nerve*-centers, thereby bringing these organs to their normal state of action At any rate its action is prompt and direct in bringing the uterus and appendages to a normal state of menstrual tonicity, when lack of tone is dependent upon some previous depression of innervation

In the following typical cases, one may see that even when the cause of the depression is still acting, this remedy will exert its stimulating power on the menstrual mechanism

Case I is that of a young woman, 18 years of age In consequence of phthisis, had not menstruated for four months Experimentally, she was given permanganate of potash As a result, menstruation occurred within a week

Case II Another young woman, 24 years of age, with an aggravating digestive trouble of some years' standing, had become very irregular, she would flow profusely for a week or two, then scantily for an equally irregular period, again, perhaps, followed without warning by a profuse flow, or, as likely, with complete cessation This state of affairs had continued for more than a year She had no dysmenorrhœa Patient was very weak and anæmic from indigestion and loss of blood She was given two-grain doses of permanganate of potash night and morning, dissolved in hot water The menstrual irregularity left her immediately, and she improved in general health at once

In young girls who are irregular in the early months of menstrual life, where it is caused by natural weakness of the partially developed organs of generation, or when, from an over-worked nervous system, the organs are robbed of their natural nerve force, permanganate of potash seems to possess the stimulating properties requisite to bring about healthy action The following is a typical case of this kind A young woman who had menstruated once, sought advice Eight months had passed and the flow had failed to appear again The permanganate was given in two grain doses twice a day Within a week she menstruated the second time in her life In two other cases of "missing menstrual periods" in young girls, without any apparent cause or any other symptoms, the remedy was given in the same dose before the next regular period was expected, which stimulated the organs to a normal flow

Since the above cases were reported, he has had many opportunities of testing the drug in similar cases, and invariably with good results From exposure to cold the weakest organs of the body will be most liable to suffer A woman who is thus exposed immediately suffers from suppression, cessation, or excess of the menstrual flow, she will invariably be found to possess susceptible and weak menstrual organs In cases of this kind, caused by "taking cold," with no other apparent cause, the most gratifying and prompt results are obtained from manganese The last described variety of cases are of so frequent occurrence that many opportunities have been offered to test this remedy, and not yet is there a failure to be recorded in either amenorrhœa or menorrhagia, when due to irritation from the effects of cold alone In several cases where the flow was a week or ten days "overdue," caused by cold, the permanganate was given in large doses, and its almost magical effect was demonstrated by the flow appearing within twelve hours

Manganese is an efficient remedy for certain forms of *menorrhagia* and *metrorrhagia*

Although menorrhagia and amenorrhœa in their outer manifestations are exactly opposite in nature, they are very often dependent upon the same causes When the cause is anæmia, or any depressing constitutional disease producing a perversion of the functional activity of the menstrual organs, and this perverted action consists of an irregular or excessive flow, this condition will as readily yield to the stimulating effects of manganese, as when the opposite condition exists The following cases are of interest

A woman, aged 26, sought advice for excessive and irregular flowing She had been married two years, she had one child twelve months old, which was large and strong, while the mother physically was of slight build, yet she nursed the child ten months and stood the strain very well, until she began to fail Suddenly she grew weak and anæmic and began to flow excessively This continued with but a few short irregular remissions until she called at the South Side Dispensary, where she was given two-grain doses of permanganate of potassium four times a day All other treatment was discontinued In three days the patient returned saying that the flow had stopped the next day after receiving her medicine She continued treatment and received permanent relief

The next case of interest was that of a large, stout woman, 35 years of age, who came to the Dispensary suffering from menorrhagia Menstruation was regular as to time, but quantity of flow was alarmingly excessive She is married and has three children, youngest 3 years of age This abnormal condition of menstruation had been coming on by degrees for a year The uterus was slightly enlarged and soft to the touch, otherwise, on making a physical examination, nothing abnormal was noticeable Four days before the expected flow she commenced taking the permanganate, in two grain doses, three times a day Menstruation came on at the expected time, and after a normally free flow for four days it passed off naturally The treatment was repeated at her subsequent periods with the same result

The above histories were written a year ago Since that time many cases of menorrhagia and metrorrhagia have been observed to succumb to the effects of manganese

The above cases illustrate well the almost magical effect of this drug upon the menstrual organs as a stimulant, and if it is properly given, much good can be obtained from its employment

Dr T Gaillard Thomas said very recently in an address delivered by him, "Permanganate of potash as an excitant of the menstrual flow is, I think, the best emmenagogue which has yet been discovered"

Dr Robert Bartholow, in a recent article on permanganate of potassium said "The powers possessed by permanganate of potassium as a general stimulant are well exhibited in the active emmenagogue, properties which it has been shown to possess by Drs Ringer and Murrell In cases of amenorrhœa, due to deficient activity, it seems to promote the function in a remarkable degree The same power which can so stimulate the sexual functions, must, when exerted in other directions, prove equally effective"

Although manganese, like the allied metals, nickel, zinc, iron and silver, has a direct influence on the blood as a tonic in anæmia, chlorosis, etc, it cannot be possible, in the writer's opinion, that its peculiar influence on the catamenia alone depends upon that virtue, for its action is too prompt To influence the organs of menstruation by acting as a general tonic, would necessarily be a slow process From the testimony of good authorities, however, it undoubtedly acts as a general tonic

Manganese can be administered in the form of permanganate of potash or the binoxide of manganese The permanganate of potash should be administered dissolved in water, and when possible, it should be taken after eating It can also be taken in dry gelatine capsules However, when given diluted, it is less likely to irritate the stomach The binoxide, although less liable to be absorbed by the stomach, on account of its insolubility, is not irritating, and can be readily administered in pill form

Dr Paoli stated that the remedy so highly lauded in the paper, he thinks was first used in London three years ago During the past two years he has tried it in a number of cases, and found it a very serviceable remedy in many cases of disordered menstruation resulting from the bad effects of either cold or dampness, yet in a number of cases the drug proved to be of no value whatever In one case he cited, the remedy was taken in one-grain pills three times a day, for a month In another case he used it two months before menstruation appeared He has also in several other cases given it in two-grain doses, but for a much shorter duration

Dr J Haven said he had used manganese in more than fifty cases, the majority of which were cases of suppressed or retarded menstruation caused by the result of cold, and he was much pleased with the results he had obtained

Dr H J Reynolds had never used the remedy, but certainly should prescribe it hereafter, after having heard the interesting paper read containing so much evidence in its favor

The Society then adjourned

LISTON H MONTGOMERY

STATE MEDICINE

HEALTH IN MICHIGAN, DECEMBER, 1884.

Reports to the State Board of Health, Lansing, by observers in different parts of the State, show the diseases which caused most sickness in Michigan during the month of December (5 weeks ending Jan 3), 1885, as follows

Number of Weekly Reports Received, 234		For Preceding Month
Diseases Arranged in Order of Greatest Prevalence	Per Cent. of Reports Stating Presence of Disease	Per Cent of Reports Stating Presence of Disease
Rheumatism	77	70
Neuralgia	72	72
Bronchitis	70	67
Tonsillitis	56	58
Consumption of lungs	54	58
Intermittent fever	53	60
Influenza	52	42
Remittent fever	40	44
Diarrhœa	36	46
Pneumonia	34	29
Erysipelas	25	27
Inflammation of kidney	23	2
Typho malarial fever	21	35
Diphtheria	19	19
Inflammation of bowels	17	19
Whooping-cough	17	13
Typhoid fever (Enteric)	16	22
Scarlet fever	15	13
Membranous croup	10	10
Cerebro spinal meningitis	9	4
Cholera morbus	6	12
Dysentery	6	10
Puerperal fever	5	6
Inflammation of brain	5	8
Measles	4	6
Cholera infantum	3	8

For the month of December, 1884, compared with preceding month, the reports indicate that inflammation of kidney, influenza, and rheumatism increased, and that typho malarial fever, diarrhœa, and intermittent fever, decreased in prevalence

Compared with the average for the month of December in the six years, 1879–1884, inflammation of bowels, cerebro spinal meningitis, influenza, neuralgia, and erysipelas, were more prevalent, and intermittent fever, diphtheria, consumption of lungs, pueumonia, and membranous croup, were less prevalent in December, 1884

For the month of December, 1884, compared with the average of corresponding months for the six years, 1879–1884, the temperature was considerably lower, the relative humidity was more, and the absolute humidity and the day and the night ozone were less

Including reports by regular observers and others, diphtheria was reported in Michigan in the month of December, 1884, at 49 places, namely Amsdon, Armada, Ann Arbor, Byron Center, Bruce, Boardman, Bloomingdale, Constantine, Cadillac, Detroit, Danby, Dowagiac, Emmett, East Saginaw, Franklin, Green Oak, Grand Rapids, Genoa, Hanover, Holly, Hudson, Hastings, Harrisville, Ingham township, Ishpeming, Kalamazoo, Lowell, Meredith, Muskegon, Marengo, Manistee, Northville, Owosso, Orange, Orleans, Pinconning, Pontiac, Porter township, Port Huron, Quincy, Royal Oak, Richmond, St Johns, Texas, Vassar, Venice, Vernon, Watervliet, Wyandotte Scarlet fever at 36 places Armada, Albion, Brockway Center, Carson City, Detroit, Dowagiac, East Saginaw, Freesoil, Fawn River, Grand Rapids, Grand Haven, Garfield, Hanover, Howell, Ida, Ishpeming, Ithaca, Kalamazoo, Leavitt, Lansing, Leelanaw, Manistee, Muskegon, Negaunee, No Muskegon, Northport, Owosso, Pontiac, Quincy, Sears, So Haven, Texas, Thornville, Westphalia, Whitehall, Wyandotte Measles at six places Detroit, East Saginaw, Fawn River, Grand Rapids, Port Huron, Whitehall Small-pox at South Boardman

HENRY B BAKER,
Lansing, Jan 9, 1885 *Secretary*

FOREIGN CORRESPONDENCE.

BERLIN LETTER.

BERLIN, Dec 20, 1884

Every practitioner here seems to be a thoroughly good pathologist, and it is quite common for a professor to prepare some elaborate microscopical slide while conversing with his pupils Thus it was at Prof Fraenkel's clinic the other day He had reason to suspect some pulmonary trouble in a patient, and in a very few moments he had prepared an excellent slide of the bacillus tuberculosis In the same way Prof Senator gave a most interesting account of the pathological history of interstitial hepatitis, and its relation to heart trouble Wolfe's public lectures every Monday afternoon, are full of practical points for the cultivation of bacilli, and their microscopical demonstration Prof Fritsch extends the courtesies of his laboratory to any physician interested in special work, he himself is engaged upon icthyological inquiries Dr Rabe Ruckard in his course of normal histology, begins with the organs on Jan 2, having finished the tissues, and Dr Immanuel Munk gives a private course to physicians in physiology with microscopical demonstration every Wednesday and Saturday evening, from 5–7 Dr Waldeyer's course does not begin until March The practical course in the physiological laboratory with vivisections has been discontinued Prof Kronecker having been called to Berne, Prof Du Bois Reymond and Prof Munk give didactic and experimental lectures The faculty and Dr Schweninger are still at sword's point The Dean, Prof Dr Leyden, went to Munich, where Dr Schweninger, as Privat Docent, had been employed in the University, and established beyond question of reasonable doubt, the truth of the many damning rumors which had followed Bismarck's physician to Berlin He submitted everything, together with the reasons which rendered it necessary for Dr Schweninger to leave Munich, to the Prime Minister, but it is doubtful if any action will be taken Meanwhile to the disgust of many the "anti-fat" doctor keeps a firm grip upon his honorary position as "Professor of Dermatology" in the University Koch has confirmed the experiments of Nicati and Rietsch, and has produced cholera in the lower animals by inoculation of the coma bacillus Of the German valuation of modified listerism, there can be but one opinion Everything surgical is done under full antiseptic precautions, and I have yet to hear of any carbolic acid poisoning, even though Dr Martin's laparotomy room is so surcharged with the spray that seeing is difficult, and many students have been unable to stand it The good results attendant upon some of the most unfavorable cases are due to no other cause, for, as a rule, German operations are not as cleanly as those in America Their technique is not any more commendable, and their facility no greater than that which characterizes our own operators Everything is done under the spray—not playing, necessarily, upon the patient, but the operating-room is kept well filled with the carbolized spray Thornton's late results in London, together with continental results and customs, are strong points in his argument against Tait, which argument, on both sides, is somewhat stripped of its interest and permanent scientific value by the bitter personalities which mar its every sentence Another great advantage is the arrangement of the laparotomy rooms, the detail of skilled assistants, and the constant association with every variety of disease calling for surgical interference The operating rooms at Charite, in Artillerie street, and at Dr Martin's private hospital, have stone floors and walls, all of which can be washed down with carbolized water, or the room can be flooded with the disinfecting fluid, if so it is willed The patients operated upon are taken to similar rooms, entirely shut off from other parts of the hospital There is even a broader field here for conservative gynæcology than there is at home Landau is making a brave single-handed fight, and for so young a man has achieved much He has a large practice, and an influence that is constantly widening He is partially supported by Gusserow, but Schroder and most of the others are quite bitterly opposed to him He is, however, a man of parts, and is leaving his impress upon German literature I cannot help thinking that Dr Landau's logic is conclusive, and that his conservatism is really more scientific and of more permanent value than the unending round of operations that characterizes German gynæcology I have heard it said that Americans were prone to resort over frequently to Emmet's operation, and I think there is truth in the assertion, but as compared with the way in which cervices are amputated in whole or in part in Berlin, for lacerations and erosions which I am convinced could be treated more rationally upon the conservative plan, our operations are only as drops in the bucket It seems to me that at this pace the number of women in Berlin with normally preserved uteri must be extremely small, indeed, the students have a saying there is not a woman living on the same street in which Dr Martin's hospital is situated who has an entire cervix uteri The temptation to resort to operation for the glory of publishing statistics and for achieving professional renown is a great one, and is inflicting incalculable injury upon gynæcology But he achieves far more, ultimately, who waits patiently and conquers symptoms by well-regulated treatment

H R B

DOMESTIC CORRESPONDENCE.

To the Editor of the Journal of the American Medical Association

In the Journal of the 3d inst appears a statement from Dr E W Jenks, of Detroit, claiming to have been the principal in making an operation which I performed and reported to the Journal of the 29th of November last Dr Jenks says "I was waited on by Dr Ranney on the 6th of October last, and received from him a description of the case referred to, and a statement of his relations to it He had assumed charge of it, and had advised an operation, which he had engaged himself to undertake It was one the importance of which he fully realized, and the realization convinced him of the advisability of having present at the operation some operator of experience "

This much is true, though I did not call upon Dr Jenks with the intention of asking him to be present at the operation I had not seen him since his removal from Chicago He had written me from Chicago a friendly letter announcing his purpose of returning to Michigan In view of our old acquaintance and cordial relations I called on him, as stated above In the course of the conversation at the time, I mentioned to him that I was going to perform ovariotomy on the next day but one The doctor asked me if I had everything I wanted I replied by saying that I would have before leaving the city "Have you a large steamer?" asked the doctor I said that I had not, but had small ones which I intended to use "Mine is all in order," said Dr Jenks, "and you can use that " He seemed to *want* me to take it, and I was "charitable" enough to do so I said I would have to provide myself with a larger trocar than I had, and he said that he had an extra large one which he would lend me He spoke of some other instruments it might be desirable to have in certain emergencies He was very cordial and his hospitality was ample I finally said ' Doctor, there is not much money in this case, and, while I do not want to insult you, I will say that if you will come down and help me, I will divide what money comes out of it " He accepted the offer I invited him, however, as a matter of professional courtesy and professional policy, knowing that should the case result fatally, "every fool would be meddling," and ' busybodies speaking things which they ought not " I was treating other patients at Grand Ledge at the time, and could manage the case in question with less trouble than I otherwise could In the course of the conversation, from something the doctor said, I feared, that, on the strength of my invitation, he considered himself "engaged to operate," as he states in his letter to the Journal So, in order that there might be no misunderstanding, I said "Doctor, I expect to *operate* myself, I want you to help " He then asked what part I wanted him to do I said, "Whatever may be required as we go on with the operation " He then remarked that he presumed there would be enough for both of us to do Said he "I would like to make the first incision." To this latter remark I made no reply, nor did I deem the matter of any importance, though he has since urged it as a strong point. There was nothing said about my not wanting to "appear as a dead-head in the enterprise," nor did I ask him to "let me do as much as possible."

Before leaving Dr. Jenks' house, I said to him that it might be well, if he had no objections, for me to take along the trocar, so that I might have it in case he should not come. He replied by saying that he would come. Early on the day of the operation I visited the patient, but before leaving Lansing, arranged with Dr. Post to come later on the cars, and that in case Dr. Jenks came to accompany him to the residence of the patient. Dr. Post asked me if the operation would be delayed in case Dr. Jenks should not come? "Certainly not," said I. Drs. Post and Jenks met on the train and came to the house together. Dr. Jenks says that he subsequently learned that the fact of his intended presence had been carefully kept from the knowledge of both the family of the woman and the local profession. Though the matter was of no special importance, I did mention it at the first opportunity I had, and also the fact that "*my large Weir's atomizer*" belonged to Dr. Jenks. On his arrival, however, he was not slow to investigate its running, and to call attention to the fact that the "machine" was his, and we were not allowed to forget the fact, for before leaving the house he in one way or another, called attention to the fact four different times. (Price of steamer $11.25.) Dr. Jenks did not see the patient till everything was ready for the operation, nor until I assisted the patient to the operating table. The husband of the patient informs me, that after the patient was placed on the table, Dr. Jenks called him one side and asked him if he was aware that his wife might not survive the operation? The husband told him that I had so informed him. Dr. Wright informs me that Dr. Jenks then called him one side and asked him if the family were aware that the patient might die on the table? I submit that it was not Dr. Jenks' business nor duty, but my own, to advise the friends of my patient of the dangers of the operation. I did not *ask* Dr. Jenks or any one else to "confirm" my diagnosis. Dr. Post administered the ether, after which I marked with an "indelible" pencil the site for the abdominal incision, and remembering Dr. Jenks' request to let him make the first incision, I handed him the knife and asked him to make it. He cut near to the linea alba and said he could not find it. I then took a probe and felt for, found it, and slightly opening the peritonæum, passed a grooved director, and together we opened it to the full extent of the external incision. We both explored the tumor. Through a large rupture in the cyst the doctor "prodded" round, as I suppose, to find another cyst, which, by exploration with my hand, I found did not exist. The doctor says: "After the tumor had been sufficiently reduced to permit its extraction, I applied Storer's shield at the junction of the pedicle and the cyst." Now, if it will be of any consolation to him, I will admit that the shield should be included in any inventory that might be made of the instruments he brought, but I do most emphatically deny that it was used, or that there was any occasion for its use.

I first grasped the pedicle with my right hand, and lifted with my left the remaining portion of the tumor through the incision. As it emerged from the abdomen it tended to draw forcibly the pedicle, and its weight made it difficult to hold. At this juncture I politely requested (but did not "instruct") Dr. Jenks to remove a portion of the tumor I was holding in my left hand, in order to diminish its weight, while we should secure the pedicle. This he did. Then, without any "instruction," though by a polite request from me, he handed me a pair of compressing forceps. They having concave jaws, would not compress the pedicle, so I requested him to hand me forceps that would tightly compress it. He then handed me a pair whose blades were less concave, but were still too much so to produce the necessary pressure. Dr. Jenks then applied a pair of straight jawed forceps, but as they were adjusted to one side of the pedicle, I politely requested him to apply a pair of forceps to the other side. Accordingly he applied a pair which included a portion of the pedicle already compressed, but not reaching to the opposite edge of the pedicle; so I requested him to adjust a pair to include that portion not compressed by the first two which he did. The jaws of the compressing forceps first adjusted were long enough to have completely compressed the pedicle had it been well adjusted, which, owing to hurry, poor eyesight, *or some other cause*, he failed to do. After the three large forceps were adjusted I had my hands full to manage them and the pedicle, especially as I had to look after another large pair of compressing forceps, which Dr. Jenks, without "instruction," or even polite request from me, attached, early in the operation, to the walls of the abdomen, from which it was dangling. It was applied to a capillary vessel, which did not even emit a jet of blood when cut. It was done before I could get to it with artery forceps to twist it. These forceps caused a large slough, and endangered the life of the patient, and would have proven fatal only for the fortunate circumstance that the peritonæum healed by first intention. With all these instruments in place Dr. Jenks handed me Storer's clamp shield, and "instructed" me to adjust it, but I politely informed him I hadn't room, and handed them back, and they were not applied. These instruments were all the doctor's, and were selected from a nice variety of others, the most of which, by the way, looked very bright and new.

The doctor says that the tumor was multilocular instead of unilocular. I do not know how he ascertained that to be true except that "*ovariotomists of experience* would expect it to be from its size, and after having discovered the peculiar consistency of its contents," notwithstanding his remark, after we were well along with the operation, that he feared the tumor was malignant! Had the "experienced ovariotomist" then discovered more than one cyst?

Dr. Jenks says: "After severing the stump, I cauterized the end thereof with my Paquelin's thermo-cautery." I never before witnessed such an ostentatious display of instruments I submit that it was not essential to mention how the metal was heated except to give notice that Dr Jenks has a Paquelins thermo-cautery I had at hand every instrument and dressing required I had disinfected my sponges and boiled my silk thread after arriving at the house in the morning The doctor brought a large number of instruments, at his own instance, but not by my request He seemed desirous of having them used in the operation He was the most "forward" assistant I ever saw at an operating table Though his officiousness was distasteful to me as it was, I think, to all present, and though his vanity blinded him to the rights and merits of others, I thought, as he was my guest, there was no harm in humoring his conceit by letting him "swash," not thinking he was attempting as "flat a burglary as ever was committed," and if I permitted him to do more than assistants usually do it was through politeness and courtesy on my part The disinfected gauze, mackintosh and wire used were my own, as were part of the instruments employed

The doctor in referring to the removal of a portion of the tumor which had escaped into the abdomen, undertakes in a most presumptuous way to "damn me with faint praise," and says that I rendered him valuable assistance in the dexterous manipulation of the sponge, that he is under obligations to me, etc Others are under still greater obligations to me for the same, for at least two pounds of the material was removed after Dr Jenks proposed to close the wound, which he says he closed by means of silver wire Now that was done by myself as much as by him, as we assisted each other in that, as in about all other parts of the operation, except when the patient bled terrifically from the cite of an adhesion when the doctor stepped back from the table and exclaimed "Doctor she is bleeding to death," repeated the exclamation and added "if you can do anything for her, do it" To this I made no response but soon had the hæmorrhage under control

Now at this juncture, had the patient died, would Dr Jenks or any one else have claimed that *he* was the principal in the case? I would not have done so, certainly He speaks of the patient's recovery being due to my carrying out his instructions! "What strong meat does this our Cæsar feed upon," that he, in his conceited pride and pedantic ignorance, lavishes upon me his "instructions" which were as gratuitous as they were presumptuous, and which were not heeded by me in the least

I assumed the responsibility of, and met every emergency in the case, notwithstanding Dr Jenks' effort to "grasp the skirts of happy (?) chance" to add to his waning laurels as a specialist

True it was something to have come from Detroit, but Dr Jenks' experience and observation should have taught him, ere this, that "promotion cometh not from the east nor from the west" I think I am safe in saying that I have done as much difficult and successful surgery as has Dr Jenks I never engaged him or any one else to operate for me I have been assisted, however, by men, who, in my estimation, were more able, but who never arrogated to themselves the credit of operating for me, even though they may have made, in the modesty of true science, a polite suggestion, nor do I think they have felt their dignity so weak, as to be impaired by acting as such assistants

The first I was made aware that Dr Jenks claimed the case was conveyed to me in the following letter

GRAND LEDGE, Nov 1, 1884

DR GEO E RANNEY

Dear Sir —Dr Messenger, of this place, has just shown me a report of my mother's case, published in the "*Medical Age*," of Detroit, which was sent him by Dr Jenks, of Detroit The report says that Dr Jenks made the operation, and mentions your name, among others, as one of the assistants What does that mean? We certainly did not employ Dr Jenks to make the operation, and the report seems unjust to you, and certainly contrary to the facts as I observed and understood them

Yours truly,
JAMES E TAYLOR

GRAND LEDGE, MICH, Nov 1, 1884

GEO E RANNEY, M D, Lansing Mich

I observed a statement in the Detroit *Medical Age*, that Dr Jenks, of Detroit, removed an ovarian tumor from Mrs Edwin Taylor, of Grand Ledge, on the 8th of Oct, which statement was indeed a surprise to me As I had treated her for some time previous, and even up to the time the operation was performed, and being informed by Mr Taylor that he had employed you to perform the operation, and knowing nothing of Dr Jenks, or that he intended to be present, I certainly considered her your patient, and undoubtedly the other physicians who assisted considered it likewise I being present at the operation, do not see wherein Dr Jenks could possibly claim the honor of performing said operation, and I write you for information

Respectfully yours,
A J WRIGHT, M D

Dr Davis heard that the operation was credited to Dr Jenks, and left word with the husband of the patient that he would like me to call on him some day when convenient I accordingly did so, when he expressed surprise that Dr Jenks should have claimed to have made the operation I then asked him to express the same in writing He was then in haste to answer an urgent professional call, and said he would write it as soon as he got home and send it by mail He accordingly sent me the following letter

GRAND LEDGE, Nov 12, 1884

DR RANNEY

Dear Sir —I was present and assisted you in a case of ovariotomy on Mrs Taylor, of Grand Ledge I understand the case has been credited to Dr Jenks, but I cannot imagine for what reason From the first I regarded you as the responsible one and principal in the case

Yours truly,
W A DAVIS

The above are statements made "in the interest of truth and honesty," by all present at the operation save one, whose verbal statement, with his permission, I would be glad to quote

GEO E RANNEY

LANSING, Jan 12, 1885

THE LIBRARY CATALOGUE AND INDEX Published by Shepherd & Johnson, Chicago

This is a very neatly prepared book, with spaces for 1,500 titles The first part of the work is ruled as a catalogue, with spaces for titles, authors' names, number of volumes, size, binding, publishers, place and date of publication, cost, position in library, and remarks The second part is arranged for an alphabetical index

When a library is thus catalogued and indexed, the owner has not only an index but a complete inventory of his books

MISCELLANEOUS

American Medical Association, Railroad Notice —The Illinois Central R R will run an excursion train of Pullman Palace cars from Chicago through to New Orleans without change for members and other physicians and their families who attend the coming meeting of the American Medical Association, leaving Chicago on Saturday evening at 9 o'clock of April 25, and arriving at the Crescent City on Monday morning at 9 o'clock the 27th The rates from Sioux City, Dubuque, Galena, Amboy, Chicago, St Louis, Bloomington, Centralia, DuQuoin, Cairo, and other points along this line, will be as low as can consistently be made It is safe to predict that this will not exceed one cent per mile each way or, to illustrate, $20 for the round trip from Chicago

Official List of Changes in the Stations and Duties of the Officers Serving In the Medical Department of the United States Army, from January 17, 1885 to January 23, 1885

Tremaine, W S, Major and Surgeon, granted leave of absence for one year, on surgeon's certificate of disability (S O 14 A G O, Jan 17, 1885)

Maus, Louis M, Captain and Assistant Surgeon, granted leave of absence for two months, on surgeon's certificate of disability, with permission to leave the Division of the Missouri (S O 16, A G O, Jan 20, 1885)

Stephenson, Wm, First Lieutenant and Assistant Surgeon, relieved from duty at Ft Omaha, Neb, and ordered to Ft Niobrara, Neb, for duty (S O 6, Dept of Platte, Jan 19, 1885)

Official List of Appointments, Promotions and Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, October 1, 1884, to December 31, 1884

Bailhache, P H, Surgeon, granted leave of absence for thirty days, Oct 9, 1884 To proceed to Wilmington, N C, as Inspector, Nov 10, 1884 Relieved from duty as chief of Purveying Division, to proceed to Philadelphia, Pa, and assume charge of the Service Dec 10, 1884

Wyman, Walter, Surgeon, granted leave of absence for fifteen days, Oct 15, 1884 Leave of absence for fifteen days in December, 1884, and thirty days in January, 1885, also for a further period from Jan 31, 1885, without pay, and with permission to visit Europe, Dec 8, 1884

Purviance, George, Surgeon, when relieved to proceed to Cincinnati, Ohio, and assume charge Nov 12, 1884, to Louisville, Ky, as Inspector, Nov 24 1884

Austin, H W, Surgeon, to proceed to Boston, Mass, and assume charge Nov 12, 1884

Smith, Henry, Surgeon, when relieved to proceed to Cairo, Ill, and assume charge Nov 9, 1884 Granted leave of absence until Jan 15, 1885, Dec 17, 1884

Stoner, G W, Passed Assistant Surgeon, relieved from duty at Delaware, Breakwater Quarantine, to proceed to Cairo, Ill, in accordance with former orders, Oct 14, 1884, to Norfolk, Va, Nov 19, 1884

Irwin, Fairfax, Passed Assistant Surgeon, to close Cape Charles Quarantine, Oct 31, 1884, proceed to Washington, and report to Surgeon General, Oct 14, 1884, to take charge of the Service port of Georgetown, D C, and detailed as Acting Chief Clerk, Surgeon General's office, Oct 30, 1884, to Philadelphia, Pa, and Baltimore, Md, as Inspector, Dec 30, 1884

Mead, F W, Passed Assistant Surgeon, when relieved to proceed to Baltimore, Md, and assume temporary charge Dec 10, 1884

Heath, W H, Passed Assistant Surgeon, granted leave of absence for thirty days, on account of sickness, Oct 24, 1884. When relieved, to proceed to Pittsburgh, Pa, and assume charge Dec 26, 1884

Guitéras, John, Passed Assistant Surgeon, to report to Surgeon General, Nov 8, 1884 Leave of absence extended fifteen days without pay, Nov 14, 1884

Wheeler, W A, Passed Assistant Surgeon, relieved at Chicago, Ill, to proceed to Buffalo, N Y, and assume charge, Dec 26, 1884

Banks, C E, Passed Assistant Surgeon, when relieved, detailed for special duty, upon completion of same, to Boston, Mass, for duty, Oct 28, 1884

Peckham, C T, Passed Assistant Surgeon, granted leave of absence for twenty days, Dec 26, 1884

Bennet, P H, Assistant Surgeon, when relieved to rejoin his station (Detroit) Nov 20, 1884

Ames, R P M, Assistant Surgeon, to report to Surgeon Hutton, at Louisville, Ky, for examination for promotion, Nov 13, 1884

Devan, S C, Assistant Surgeon, to proceed to Tacoma, W T, as Inspector, Oct 14, 1884

Kalloch, P C, Assistant Surgeon, granted leave of absence for thirty days, Nov 19, 1884

Glennan, A H, Assistant Surgeon, to proceed to Key West, Fla, for temporary duty Oct 8, 1884

Battle, K P, Assistant Surgeon, granted leave of absence for thirty days on account of physical disability, Dec 6, 1884

Brooks, S D, Assistant Surgeon, to proceed to New York, N Y, for temporary duty Oct 20 and Nov 26, 1884

White, J H, Assistant Surgeon, to proceed to New Orleans, La, for temporary duty, Oct 3, 1884 To escort insane seamen to Government Hospital for the Insane, Dec 17, 1884 Granted leave of absence for fifteen days Dec 23, 1884

RESIGNATION

Smith, Henry, Surgeon, resignation accepted by the Secretary of the Treasury, to take effect Jan 15, 1885 Dec 17 1884

APPOINTMENT

White, Joseph H, M D, of Georgia, having passed the examination required by the Regulations, was appointed an Assistant Surgeon by the Secretary of the Treasury, Oct 2, 1884

PROMOTIONS

Peckham, C T, Passed Assistant Surgeon, promoted and appointed Passed Assistant Surgeon by the Secretary of the Treasury from Dec 1 1884 Nov 28, 1884

Ames R P M, Passed Assistant Surgeon, promoted and appointed Passed Assistant Surgeon by the Secretary of the Treasury from Dec 1, 1884 Nov 28, 1884

Devan, S C, Passed Assistant Surgeon, promoted and appointed Passed Assistant Surgeon, by the Secretary of the Treasury, from Dec 1, 1884 Dec 5, 1884

Urquhart, F M, Passed Assistant Surgeon, promoted and appointed Passed Assistant Surgeon by the Secretary of the Treasury, from Dec 1, 1884 Dec 5, 1884

THE WORTHLESSNESS OF INHALERS AND INSUFFLATORS IN THE TREATMENT OF CHRONIC NASAL CATARRH

BY THOS F RUMBOLD, M D , OF ST LOUIS, MO

Almost every work that has been published within the last five years on diseases of the nasal passages and throat contains full directions for using these methods Inasmuch as I know, from experience, that both of them are not only worthless but injurious, I will analyze the subject sufficiently to demonstrate their inefficiency, and show that they must do harm in every instance, even if the agents used are the very best that could be selected, proving conclusively that the failure to benefit the patient is due wholly to the fact that the methods themselves are defective I will go farther, I will give my experience to prove that the agents usually employed are deceptive, and are always injurious

In the early part of 1868 I saw, in Cohen's work on inhalations (1867), a lucid description of Lewin's (Berlin) method of making and applying nascent muriate of ammonia This method of applying this salt to the diseased mucous membrane appeared so scientific, and was so highly recommended, that I got an elaborate apparatus prepared, and employed it for nearly one year on a large number of patients, consequently my knowledge of its effects is not merely theoretical but experimental

As this method is again being revived, I will quote Cohen's description of Lewin's apparatus, to show that what I used in 1868 and what is now being used are one and the same

"This apparatus [fully illustrated on page 251] consists of a series of three Wolfe's bottles One of these contains liq ammoniæ caustici, another pure muriatic acid, and the third bottle, which is filled with water, receives a tube from each of the other bottles, these tubes reaching to the bottom of the water, while from a third opening in the cork the vapor extrudes through an exit tube, to which a mouthpiece is attached by India rubber tubing Now, as the effort of inspiration draws the liquids [vapors] from the first two bottles into the third bottle, their ingredients combine to form the sal ammoniac vapor, which, during its passage through the water, becomes cleansed of impurities If it is desired to medicate the nascent sal ammoniac with creosote, or an oleo-balsamic mixture, or bitter almond water, etc , all that will be necessary will be to add it to the water in the third bottle "

I followed these directions to the letter In the third bottle—that is, the one from which the patient inhaled the nascent muriate of ammonia—I put the "oleo-balsamic mixture, bitter almond water, etc " The "etc " consisted of almost everything that would evaporate and not do harm, but the three agents from which I received the most benefit, or rather that made the patients think they were receiving the most benefit, were carbolic acid, cubebs, and sassafras bark, named in the order in which they gave the most satisfaction

I found in a month or two that the patients were under the influence of a continuous cold in the head, a symptom that many of them had not before experienced I then gave the inhalations but once a week, and in the interim I applied, by means of such spray producers as would treat the pharyngo nasal and nasal cavities, about one half dram of the following mixture Saturated solution of muriate of ammonia, tincture of iodine, tincture of aconite leaves, of each ʒj, and water ℥viij Gradually I lengthened the interval of the inhalations, until I stopped them altogether at the end of the year 1868

The first few times that these inhalations were used the patients were greatly pleased with them, but the pleasant effects soon faded into unpleasant effects, which, with the increase of symptoms of acute inflammation, proved to me that the method was an injurious one

The Kirkwood and Crosby inhalers, and the one now popular in London (I have forgotten the name of the claimant of this one) and recommended by an ear surgeon of that city of some note, are apparatuses for the formation of nascent muriate of ammonia, and are precisely alike in principle to the one used by Lewin, in 1862 The London apparatus is so constructed that one bottle is all that is required Through the cork of the bottle are passed two tubes One is made Y-shaped, the lower portion of which passes through the cork and to the bottom of the liquid in the bottle In one of the projecting arms of this Y-shaped tube is placed a small sponge, on which is poured muriatic acid, into the other arm another small sponge, on which is poured aqua ammonia The other tube that passes through the cork is used by the patient for inhaling the vapor from the bottle

Each one of the inventors (?) has placed in the fluid that is in his bottle some agent that is apparently intended to enhance the value of the muriate of ammonia, such as carbolic acid, cubebs, camphor, tincture of iodine, chloroform, and such like

The strength of the carbolic acid is always sufficient to produce an anæsthetic effect, anything short of this would not serve their purpose, which is to have their purchasers experience a relief of any pain that their catarrh might cause, but whenever this anæsthetic effect is produced, it *always increases* the existing congestion of the mucous membrane I am very certain that I am right in making this assertion Not only does the carbolic acid increase congestion, but if any irritating agent is also put into the inhaler, as the tincture of iodine, the patient is not warned of the injury done by it, as the pain is covered by the anæsthetic property of the acid In some of these apparatuses chloroform also forms a part of the liquid, this agent will certainly cover all irritation produced by the tincture of iodine That this latter agent is always injurious may easily be proved by the reader inhaling it alone, the immediate increase in the flow of mucus makes irritation apparent

Only those who have applied cubebs and camphor to their own nostrils know how liable both of these agents are to render the mucous membrane subject to colds Hot water baths are not more liable to induce colds than cubebs and camphor If they are to be used, I would advise the physician (especially if he has the least nasal catarrh — for they will not have a very bad effect on a healthy person), to use them on himself first

Insufflators are far more popular than inhalers I presume that the reason for this is that a powder from the former instrument remains much longer on the mucous membrane than a vapor, consequently they may think that applications by an insufflator will have a more permanent curative effect

All the agents named, except chloroform, the least objectionable one, are also used in the insufflator In fact, they are the principal agents, and upon them the authors of our latest works on diseases of the nasal passages depend for the cure of chronic inflammation

If these are taken away, their books would be stripped of remedies that give as much, if not more, promise than all other agents that they recommend

It is admitted that vapors from an inhaler, and powders from tubes called insufflators, can be made to pass through the nasal cavities, not only this, but they can be thrown upon every portion of the nasal surfaces But experience has proven time and again that they have not cured chronic catarrhal inflammation Why is it that these methods do not cure?

Some one may say, "If every portion of those irregular cavities is reached, the failure must be due to the fact that the wrong agents are employed" Unfortunately this is not a satisfactory explanation of the failure, because every article of the materia medica that could be used and would not produce positive injury, has been applied by one or both of these methods, and with the same general result — a complete failure

It seems to me that this indicates that the objects to be attained and the means of attaining them are not understood, or to use other words, that what is to be done to treat nasal catarrh successfully, and how to do it, are unknown A proper understanding of these two paramount subjects is, I think, the solution of the whole difficulty

I will endeavor to answer the question What should these two methods do to assist the healing tendency of nature to perform a cure?

Every one familiar with the appearance of a chronically inflamed mucous membrane, knows that it is usually coated with a thick tenacious secretion, and in the worst cases this muco-pus sometimes forms crusts Many years of experience has proven most conclusively that success in treatment will depend on the removal, by mild means, of this closely adhering coating, which, besides being a constant cause of irritation to the membrane covered by it, is a source of very much annoyance, and frequently of great pain, and it prevents the medicament from reaching the diseased surface, a most important matter, as every one will perceive after a moment's reflection

It is self-evident that the inhalation of a vapor, either cold or warm, or the insufflation of a powder, can have no cleansing effect on a surface that is even but slightly affected by catarrhal inflammation, and as to its cleansing surfaces covered by secretions, some of which adhere so tenaciously that they can scarcely be removed by a brush, cannot be thought of for a moment, yet this is just what is expected of them, what they should do and what they *must do*, if the case is to recover by the aid of this kind of treatment

I venture to say that it is now not difficult to understand why the inhalation and insufflation methods of treatment always fail

Besides this palpable oversight, there is another nearly as great, it is this In the immediate neighborhood of the inflamed parts, there is quite an extensive surface of healthy mucous membrane This normal membrane is constantly moistened with a VERY THIN coat of healthy mucus, which is watery in its consistency I have not emphasized the words "very thin," accidentally, but to indicate the extreme attenuation of mucus on a healthy mucous membrane Chemico-physiologists have been unable to ascertain the exact chemical composition of healthy mucus, for the simple reason that it was impossible to collect a sufficient quantity to analyze it, proving, conclusively, that the quantity on the healthy membrane is only sufficient to moisten it, not the least redundancy is to be found on its surface

A vapor from the inhaler or a powder from the insufflator instantly affects the healthy mucous membrane through this attenuated coating of healthy mucus, but I deny that we have any evidence that even a pungent vapor, or a sharp powder will as quickly pass through so much as a thin coating of secretion that flows from a catarrhal surface, and as to a powder passing through a thick, viscid muco-pus (for a vapor cannot do it) I know, from observation, that hours and days are required The rain falls upon the just and the unjust, so, with like impartiality, does the vapor or powder light upon the healthy and unhealthy mucous membrane, but their effects upon these two different surfaces stand in marked contrast to each other

A vapor or a powder can produce no effect in the nasal cavities unless it reaches the mucous membrane by being first formed into a solution by the mucus that is on the surface to be treated Surfaces covered by crusts are of course not affected in the least by either agent, yet this very surface is more in need of treatment than any other If a membrane, covered by a semi-fluid, tenacious muco-pus is to be treated, it can only be done by the vapor or powder being formed into a solution by this thick secretion It is safe for me to say that no vapor, however pungent, penetrates this muco pus, and it is also safe to say that a powder may remain on it for several days without affecting the membrane covered by it Can it be said that this exemption from the effects of a vapor or powder is extended to the healthy mucous membrane? No, indeed! The healthy mucus instantly forms a solution of both, so that the healthy membrane is as instantly injured by it I presume no one will say that a healthy mucous membrane may have a medicated vapor or powder applied to it repeatedly without injuring it

"But," says a friend of the inhaler and insufflator, "I have seen crusts as well as semi-fluid secretion removed by both of these methods How do you account for it?" In this way The vapor and the powder always acts as an irritant to the healthy mucous membrane, as has been said, and, in the instances where these accumulations were removed, the irritation must have been of such an aggravated character, as to be sufficient to excite an unusual flow of mucus from the *whole* surface of the nasal cavity, that is, the mucus is caused to be poured out from that portion of the membrane that is covered by the crusts and semi fluid secretion, as well as from the healthy uncovered membrane, and this unusual, forced outflow of mucus washes away a part of the adhering muco-purulent collection That I am right in this, is proved by the fact that these solid and semi-solid accumulations come away long before a powder could have passed through them to have such an effect on the membrane to which they adhered This is evident Again a vapor, an agent that no one will say can pass through these secretions, will in precisely the same way and in the same time remove these accumulations

There are two important questions to be asked

1st Has a diseased surface, that has been treated by the inhaler or insufflator, been benefited or irritated by these methods?

A surface thus covered could derive no benefit from a vapor passing over it, the duration of the passage being too short, even a powder would not remain there long enough to become a solution of sufficient strength to excite a flow of mucus to wash off the coating, because the portion of the powder that fell on the healthy mucous membrane would cause enough irritation to wash everything out of the cavity Consequently the answer must be that the diseased surface was irritated only, not by the medicament applied to it, for that could not reach it, but that applied to the healthy mucous membrane in its immediate neighborhood

2d Has the healthy mucous membrane been benefited or irritated?

I should like to know which horn of the dilemma the advocates of inhalations and insufflations would take? For either will injure their cause They do not wish to be understood as making applications to a healthy surface for the purpose of improving it They can only say that they unavoidably irritate the healthy surface, while irrigating the diseased membrane sufficiently strong to compel an unusual flow of mucus to wash away an offending secretion

"But," says one, "I deny that there is any healthy mucous membrane in a catarrhal nasal cavity" Will he, in this way, get rid of these two barriers (questions) to these methods? No, indeed! Even if his knowledge of the condition of a catarrhal nasal cavity is limited, which this denial would indicate, he must admit that there are portions of a catarrhal cavity that are far more inflamed than others, that is, there are portions that are not covered by semi-fluid and solid secretions This being the case, as all know, then let him answer the questions as to the treatment of the less, and the more inflamed parts, by a method that treats the covered portions by irritating the uncovered portions

It is seen that the surface that does not require treatment receives it, and that which does require treatment does not receive it Irritating a healthy membrane for the purpose of influencing a diseased membrane, cannot be called treatment of a diseased membrane These methods irritate the healthy surface to free the unhealthy surface of its diseased secretion, the injury done to the one is much greater than the benefit to the other, for a healthy membrane, will take on an inflamed condition very much faster than a diseased surface will resume its normal condition

Some one may suggest that if the catarrhal secretion be first removed, might not a vapor and powder have a beneficial effect?

No, of course not! I have already given my experience to prove that the vapors and powders mentioned in this paper (and they are the most popular), are harmful in whatever way they are applied

The consideration of vapors is dismissed by saying that they are too transient to be beneficial

It is impossible to apply a powder to a diseased surface alone, and the healthy surface will be injured by a medicated powder Even the mildest kind of a powder will cause irritation of a healthy membrane by drying its surface, which is not its normal condition, this condition being that of perpetual moisture In this case, also, the injury done to the healthy surface by the medicated powder is greater than the benefit to be derived from its application to the cleansed diseased surface

If a patient's nasal passages are cleansed first, and a powder applied next, the case will be over-treated Those who have had much to do with these cases, know how easy it is to over-treat them If the patient is made to wait long enough for the membrane to recover from the partial injury done by the cleansing process, as water cannot be applied to the nasal mucous membrane without injuring it to some extent, the surface will be again coated with secretion before the powder is applied, in which case the patient will not be properly treated

That physician is exceedingly fortunate who can do ANY THING to a patient's nasal passages, and leave them in an improved condition This remark will be appreciated by those who have had experience with these cases

---

"MEDICAL JURISPRUDENCE IN DIVORCE"

BY CARL H VON KLEIN, A M ,M D , DAYTON, OHIO

An address delivered (by invitation) before the "Ohio State Bar Association, at their annual meeting Dec 30 and 31, 1884, Columbus O

MR PRESIDENT, GENTLEMEN OF THE OHIO STATE BAR ASSOCIATION

No branch of science seems to have been more neglected than that pertaining to Medical Jurisprudence in Divorce Will you, then, pardon my zeal upon this subject? I do not desire to bring to your attention, gentlemen of the bar, a subject with which you are unacquainted, nor is it my object to send this address to the forensic world as upon a new field of science But rather as an attempt to show what beneficial effects might result from a more thorough and scientific study of the subject My humble judgment leads me to believe that many cases of divorce are obtained improperly from the very fact, known to laymen, as well as to your own and my profession, that the point of Medical Jurisprudence is very seldom raised It may sound absurd, yet the fact can not be denied that two-thirds of the cases in divorce are obtained on the ground of willful absence Though it may remain unadmitted, nevertheless I will assert, that in almost every case where willful absence is the alleged ground of divorce, if the predisposing cause were carefully ascertained, it would disclose the fact, that impotence or some organic perplexity, either local or constitutional was the prime cause Yet have any of you ever heard of a court that inquired into the prime cause of a wife or husband's willful absence? Right here I would like to be informed of the truth of this matter, that it may enable me to place you aright before the eyes of the world It would afford me great satisfaction to know that many of you who are very eminent in your profession can vindicate yourselves honorably from the charges which I am now about to make, to wit a claim to superior wisdom and infallibility It is a common thing for a lawyer to claim to be the most learned man in the land, from the very fact that he ought to be The progressive scientific lawyer is demanded not only to be well posted in jurisprudence, but he must be no stranger to botany, chemistry, pharmacy, microscopy, physiology, anatomy, surgery, medicine, and its collaterals His application must be indefatigable, and his attention to the operations of nature equal with that of a physician—a philosopher in the true sense of the term It is not demanded of a physician to understand law, but it is emphatically required of the jurist to understand physic I will again pray you to pardon my rude charges against your chosen profession, but it is the truth! "A very little truth will sometimes enlighten a vast extent of science" You may truthfully state that it is impossible for one human mind to accomplish all the branches of science especially demanded by your profession, but there is no excuse for you to ignore our profession Since you cannot accomplish the entire science of your occupation without our aid, so essential to your assistance, you must, therefore, regard us a part of your profession In order to prove that a physician is ignored by intelligent courts of judicature, I will show the following cases

CASE 1 Mrs B, an intelligent lady, age 26, a handsome brunette, applied for divorce to the County Court of Cook Co, Ill, in 1872, on the plea of willful absence When the case was called, the defendant aimed to prove that it was a necessity for him to be parted from her, but he did not care to be divorced But the court ignored this, and a divorce was granted In 1874 she applied to a physician for treatment for some acute malady After he became well acquainted with his patient, he discovered by her admission that she was once married, and loved her husband, but she had lost her sexual desire, and venereal intercourse had become almost as a death warrant She did not even care about being restored, but after expostulating with her for some time, she consented to treatment She was entirely restored in the course of nine months, when she again renewed her marriage with her former husband

CASE 2 Mrs L, age 22, applied to the County Court of Wayne County, Michigan, for a divorce on the same ground as in the former case She related a peculiar history She stated in her petition, after the second night of her marriage her husband left her bed in the middle of the night and had not returned for three years or longer, for a cause that she did not know But she admitted in court that the fault was her own which caused him to leave her She testified that she had a boil in the vaginal cavity, and that she could have no connection with him, and for refusing indulgence to his venereal pleasures, he left her But she loved him and would do so to day, and he would live with her, provided she could perform sexuality Nevertheless a divorce was granted A friend advised her to consult a physician, which was done, and she permitted an operation which restored her to her normal condition by removing three large polypi, each one weighing almost an ounce and a half She also remarried

CASE 3 Mrs D, age 31, married nine years, applied for divorce in New York County Court, on the usual ground of willful absence She claimed that her husband did not like her, and during all the period of their marriage there was no sexual intercourse between them, she claimed that she liked him and would live with him, if she could raise a family The defendant also admitted there was no such intercourse between them, that he would live with her if he was able to accomplish the same Here the greatest circumspection of medical jurisprudence should have been demanded, but neither the jurist nor the judge of such an enlightened court as New York, demanded or ascertained the incapacity of the unfortunate man, and a divorce was granted. In accordance with the plea of the plaintiff, in a short time after, he consulted a physician who found him to be afflicted with capistration, he was immediately relieved by a surgical operation. He went to see his former wife and they were remarried six months after the divorce, and are now living together happily with a family of two or three children.

There are thousands of cases of the same nature that are neglected by the ignorance of the faculty, the caprice of the court, or by the artifices of either or both. From the foregoing and the continuation it can and will be seen, that medical jurisprudence is necessary in almost every case of divorce, but no books in the world will ever make an expert to facilitate the learning of it. It should excite the most strenuous endeavor of those whose business it is to instruct others in the medical science, the utility of which has been confirmed by a long, extensive, and painful experience. Such as they are, mankind are welcome to them, for medical men have no other object in view but human benefit. He who can conceal that which would be advantageous to thousands for the emolument of a paltry individual, is a despicable wretch that deserves very ill of society.

> "Si quid novisti rectius istis,
> Candidus imperti, si non his utere mecum."
> *Horat.*

There[1] are many disorders which are generally allowed to constitute the natural grounds for a divorce between two married persons, though particular laws are generally founded on local causes, and probably do not refer to their natural reasons, yet no others concern the medical portion. There are many disorders, by whatever name they may be called, all defects of the human constitution, which appear to constitute the natural reason for a divorce, generally those which are absolute impediments to procreation, these may be considered in accordance with the subject of generation, and may be classed technically under two heads, *impotence* in men and *sterility* in women, which is either positive or perpetual, or such as defies human art to remove. We consider absolute impotence in men when they are eunuchs, or are deprived of both testicles, as these are the receptacles of semen; without them no generation can be performed; or spadones, such as have the nerve or muscle leading to the parts of generation bruised so as to deprive them of all perception of a venereal appetite; or when the penis is perforated in such a manner that the semen can not be emitted with sufficient force. This rule is to be admitted with some limitation, as the theory of generation is not sufficiently established. Even when the penis is too short, by being amputated for disease; or when the penis is too thick, these cases may be respectively considered; when both testicles have become scirrhus, so as to be incurable, or the vesicula seminales have become scirrhus; or the semen is too watery, and will not admit of alteration, nevertheless, it is not an absolute cause, as it admits of a cure; when they are afflicted with capistration, or the preputium is so formed or fastened to the glans penis that it cannot be relieved by a surgical operation. All disorders which are impediments to procreation of children, and which are not caused by the organs of generation; such as are of a highly contagious nature, or create an unconquerable aversion, as the lues veneræ, melancholy, epilepsy, scurvy, scrofula, and a highly fœtid and disagreeable breath. Absolute sterility in a woman, disqualifying her to perform sexuality, will arise when the parts ordained for the organs of generation are such that they do not admit of relief without great jeopardy of life; when the vagina is too straight and narrow; on account of scirrhus tumors, etc.; which may be impossible to remove; when the orifice in the uterus is entirely closed. This is not an absolute impediment, because it may be remedied by the hand of a surgeon.

When there is an ulcer in the uterus, which might have penetrated the rectum and bladder, even when oppressively afflicted with leucorrhœa or whites, great care and attention should be given before an absolute judgment is rendered, as this admits a cure; but if everything failed, the husband should also be examined carefully in regard to his own adequacy. There are many other causes of sterility, which are caused by obstructions or injuries in the organs of generation; but it is all darkness, and it would be inhuman to determine by any other method than by the inspection and careful examination of the parts by some scientific and honorable physician. There are, besides these, many other circumstances that may not render either sex absolutely impotent, yet may be considered defective. There are certain obstructions to the generative organs that in no way constitute reason for divorce. Ignoramuses may consider them as such, but the progressive physician will guard against such an error. The following occur in the male sex. Monorchides—such as have only one testicle. These are by no means incapacitated, as this secretion is only made in that organ, from which it is carried to the vesiculæ seminales, and there deposited for use, so that one testicle is as effectual as two; the secretion is always proportionate to the evacuation. Triorchides — those who have *three* testicles; spadones, where one testicle is injured. Chrysporchides are those whose testicles do not lie in the scrotum, but in the abdomen or in the groin; those who have præputium buttoned on the glans; those who labor under phymosis, or paraphymosis, a disorder where the præputium is brought over the glans penus or contraction of the prepuce behind the *corona* in such a way as to prevent its return over the glans, and cannot be retracted but by art; those whose penis is shorter or longer than natural, unless extremely so; those who are circumcised. *This is* an advantage rather than an impediment. Hermaphrodites, or Androgyni. Those are unfortunate living beings, sometimes capable of all the functions of society. Yet their situation should arouse our pity, for they are not only deprived of common pleasures of mankind, but are subject to disorders, painful, uncomfortable, incommodious, constantly having desire when in society of either sex. A perfect hermaphrodite has distinguished marks of both sexes, with a power of enjoyment with each. An imperfect hermaphrodite may be classed according to the sex, into what are called Androgynus and Androgyna.

---

[1] According to Johanus Fredericus Faselii in his work entitled "Elementa Medicinæ Forensis." Geneva, 1702.

The former is the male, who has his own organs tolerably perfect, but has some division in the flesh above and below, or in the scrotum, which makes an appearance of the female pudendum. The penis may also be obliterated so as to give no exterior appearance of the male, but the general constitution of the body, whiskers, etc., confirm him to be of that sex.

The Androgyna is a woman who has the parts of generation nearly like another but, at the same time, the clitoris grows so large that it has the form of the male penis. This may be a very inconvenient disorder, as she is sometimes deprived of pleasures peculiar to her sex and suffers much from the disorders of the parts. From her mammary glands and imperfection of beard, however, she is distinguished from the male. As a rule such women are subject to robust and masculine constitutions. It is evident that those sexes are as completely marked as in other persons, and to all legal intents and purposes, they are men and women. Women are claimed to be incapacitated entirely, as the various disorders of anteversion and retroversion, anteflexion and retroflexion of the uterus may be only temporary, and may be remedied by art, when they have too large a clitoris or nymphæ, or when they are androgynæ or hermaphrodites, from various causes, where the pudendum is too large and wide, when they are irregular menstruants, or have received a rupture of the perineum, or the part between the fundament and pudendum, etc. I will not enter into further detail, as there are many other points which might be raised in jurisprudence, but, in conclusion to my foregoing, I shall narrate to you, as well as to my professional brethren, the improvements of this science. I am sure they can have no objection to my course. The love of truth is of equal importance in the reception of facts and in the formation of opinions, and it includes, also, a readiness to relinquish our own opinions when new facts or arguments are presented to us which are calculated to overthrow them. Let us inform ourselves with all the modern education of the present day. Lord Bacon says: "Knowledge is more beautiful than any apparel of words which can be put upon it." Let us investigate that which we have neglected, and acknowledge the errors, which we lamentably regret, and unite our attainments of science [illegible]ver language we may use. In natural scien[illegible] but one language universally intelligible [illegible] language of facts belongs to nature here, there[illegible] I trust that the forbearance of the past will be gr[illegible]vitated by the future, and we can rest assured that the most excellent and refined felicity springs from the disinterested and varied endeavors to lessen the evils of life and add to the enjoyment of our fellow-citizens.

TREATMENT OF DIPHTHERIA

BY JOHN M. BATTEN, M.D., PITTSBURGH, PA.

During the last few years my recoveries of cases of diphtheria that I have treated have been 80 per cent. The remedies I have usually prescribed were chlorate of potash and tincture of the chloride of iron internally, with liberal sustaining diet and large doses of whisky at stated intervals. The local treatment consisted of gargling, penciling, or spraying the throat with a saturated solution of chlorate of potash, but latterly I have used lime water instead of the solution of chlorate of potash, and found it quite a beneficial local remedy.

The physician, in order to be successful in the treatment of diphtheria, should see the patient at the commencement of the disease. The patient should be put immediately to bed in a large and well ventilated room, on the second or third floor. The temperature of the apartment should be about 65° F., the air of which should be kept moist by means of boiling water in a tea-kettle or other vessel, or by placing unslaked lime in a bucket over which boiling water may be poured. The patient should remain in bed till all danger of the sequelæ of the disease are past. All secretions of the mouth and throat should be expectorated or washed out, and the throat and mouth should be rinsed or sprayed frequently, either with cold water, a solution of chlorate of potash, or with lime water. If the mouth and throat are parched, small pieces of ice may be allowed to dissolve in the mouth; strong caustic solutions of any kind should not be used. All the local applications should be of a soothing, solvent, or antiseptic character.

If the exudation extends along the nasal tracts, they should be washed out with lime water or a solution of chlorate of potash by means of a nasal douche. When the exudation has disappeared from the throat, tincture of the chloride of iron in full doses may be administered three times a day, and sweet cider taken *ad libitum*. The latter remedies I think counteract any tendency to congestion of the kidneys and consequently albuminuria. If, by reason of swelling of the throat, paralysis of the muscles of the pharynx, or irritable stomach, the patient becomes unable to swallow, suitable remedies should be directed per rectum.

When the throat is much swollen, bags of ice may be applied to it, or, if more agreeable to the patient, hot fomenting poultices may be used instead of the ice. The diphtheritic membrane should be allowed to come away without forcibly dragging at it.

The temperature usually the first few days of the disease rises to 102° F., then it declines to normal or below it, when it may again rise above normal. It is when the temperature declines below normal that stimulants act so beneficially, and if not given at any other period of the disease they should be given then, but, as I have stated before, I give whiskey throughout the disease.

The so-called specific remedies are mercury, sulphide of potassium, bromine, and the balsam of copaiba and cubebs I have had no experience with any of the above named remedies except mercury, and would not administer it only in a case of laryngo-tracheal diphtheria or the so-called pseudo membranous croup In a malignant case of pharyngeal diphtheria I certainly would not administer mercury, because I believe other remedies would give better results

The general antiseptic remedies are the tincture of the chloride of iron, chlorate of potash, carbolic acid, and salicylic acid with its compounds The value of iron and chlorate of potash I have already referred to Dr Mackenzie states that sulpho-carbolates as referred to by Sansom have proved beneficial in his hands only in secondary poisoning of diphtheria Five grains of the sulpho-carbolate of soda in water may be given to a child of two years every three or four hours Salicylic acid has been used by Fontheim, who highly recommends it Salicylate of soda and potash have been found of doubtful efficacy in the treatment of diphtheria

Of the local solvents, Steiner recommends particularly lime water Sanne has recently suggested saccharate of lime The solvents can be applied to the membrane by means of a spray apparatus or camel's hair pencil Mackenzie states that lactic acid is a most reliable solvent, and that he applies it freely with a brush

As local antiseptics, carbolic acid, permanganate of potash, chloronated soda, glycerine of borax, and hydrated chloral suitably diluted have been recommended The antiseptics may be gargled or used by a spray apparatus Varnishes act as antiseptics by excluding the air from the false membrane, and have been recommended and used by Dr Mackenzie They consist of gum benzoin, gum tolu, mastich and resin, either of which may be dissolved in rectified spirits of ether He prefers ethereal solutions (1 to 5) and tolu as most pleasant, and lasts longest as a varnish It is applied by a brush after the false membrane has been dried by blotting paper

Until recently I believed that laryngo tracheal diphtheria, and the so-called pseudo membranous croup, were two separate and distinct diseases I think now they are one and the same disease To substantiate me in my opinion as to the unity of the so called pseudo-membranous croup and diphtheritic croup, I refer you to an article written by Alex Harris, M D, page 330, Vol 1, No 11, JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION I have observed the so called pseudo-membranous croup treated with emetics, and have witnessed the patient vomiting from the effect of these drugs, and never have I known a patient recover by this mode of treatment Of course, if we have reason to believe the membrane in the larynx or trachea is loose, then a brisk emetic may remove the exudation, otherwise it will do harm

In a few cases I have prescribed one grain of calomel every two hours, and my patients so treated recovered Twelve years ago my attention was directed to the beneficial effect of this remedy in this disease I was attending professionally a boy, five years old, suffering from so-called pseudo-membranous croup I prescribed the regular routine of expectorants and emetics, and my patient grew worse, till I thought it a proper case for surgical treatment An experienced and skilled surgeon was called to see the case with me, who gave it as his opinion that the case was a proper one for tracheotomy It being late in the evening, and the parents of the patient not having consented to have the operation performed, we determined to postpone the operation till the following morning A grain each of calomel and pulverized ipecac was directed to be given every two hours, and the inhalation of steam from lime The following morning, I was notified my services were no longer required The family, a short time after my dismissal from the case, called in an irregular, but the calomel powders, in the meantime, were administered according to directions Shortly after the irregular saw the boy and had administered a few sugar pellets, the membrane was expectorated and the child recovered The calomel did its work, and the irregular got the credit of curing the disease

Recently I attended a boy, six years old, suffering from diphtheritic croup I administered calomel in grain doses, every two hours, with inhalation of steam from lime The patient recovered *Dr Wm Pepper* has lately reported a like success in the treatment of a case of laryngo-tracheal diptheria with mercury

---

A CASE OF VICARIOUS CATAMENIAL HÆMORRHAGE FROM THE GUMS, WITH RECESSION OF THE GINGEVAL MARGINS AND ALVEOLAR PROCESSES, THE RESULT OF AMENORRHŒA

BY W W ALLPORT, M D, CHICAGO, ILL

[Read to the Section of Oral and Dental Surgery of the American Medical Association, May, 1884]

MISS K W, aged 25 years, of tall, slender form and nervous temperament, has been under my professional care for the past twelve years As a girl she enjoyed average good health, several years ago noticed a tumid condition of the margins of the gums, which were also detached from the necks of the teeth, and slightly receded, accompanied with a tendency to hæmorrhage on mastication, or when using the tooth-brush

Upon a careful examination, could find no deposits of salivary calculus about the necks or roots of the teeth, nor could I discover any discharge of pus Pressure, however, upon the congested portions of the gums, caused slight hæmorrhage The case was treated at that time by free scarification of the gingeval margins, and astringent washes The young lady has been seen at frequent intervals during the intervening years, and the same treatment substantially adopted, but with only temporary benefit

I had noticed, however, that she was gradually losing her health, and rapidly falling into a nervous, moody condition, and suspecting uterine trouble, therefore advised consultation with her family physician, but this advice had been neglected In October, 1883, was again consulted regarding the condition of her teeth and gums, found them in very much the same condition as already described But the recession had gradually progressed until the necks of the teeth were considerably exposed, and the teeth very slightly loose in their alveoli The general appearance of the patient was decidedly anæmic, and she complained of the hands and feet being habitually cold, pain and weakness in the lower lumbar region, easily fatigued, and that once in six or seven weeks her gums would bleed constantly for from two to three days—the amount small, but still enough to tint the saliva I found also, upon further questioning, that she was suffering—and had been for the past seven or eight years—from a uterine derangement, causing irregularity in the appearance of the catamenia

The history of the uterine difficulty is as follows Commenced menstruation at fourteen and a half years of age At first, menses were free, and unattended with pain, but habitually delayed from two to four weeks This condition continued for nearly five years, when, at the age of 20, a period of six months elapsed without any appearance of menstruation Since that time the menstrual periods have been rather more delayed than formerly, with gradually decreasing flow and more general disturbance As the period of menstruation would arrive, she would be troubled with the hæmorrhage from the gums, already mentioned (occasionally accompanied with nose-bleed), dull headache and increasing languor, these symptoms subsiding on the appearance of the menstrual flow The case was therefore referred to the family physician, Dr J S Hotchkiss, who found, upon examination, the following conditions Vagina quite small, uterus in a retroverted position, with the cervix anteflexed, was unable to pass the sound into the cavity of the uterus on account of the sharp flexion of the cervix

The treatment has resulted in correcting the uterine difficulty During this treatment the Faradic current was used about the pelvis, and the patient prescribed iron and cod-liver oil Improvement commenced after the first week of treatment, and continued steadily The first and second menstruations occurring after the treatment was begun were delayed till the sixth week, but were free, and unattended by any general disturbance At the third menstrual period there was a slight show at the fourth week, but it came more freely at its accustomed time, the beginning of the sixth week

When last seen, a few weeks ago, the patient's appearance gave indications that her health was in every way greatly improved

The hæmorrhage from the gums has not occurred since the reestablishment of the menstrual flow, the gums have their normal color and attachments (except that they had not regained their normal position at the necks of the teeth)

The mouth is now in a healthy condition, and this result has been accomplished with no other treatment than that adopted by her family physician for the amenorrhœa

DISCUSSIONS ON DR ALLPORT'S PAPER

Dr Marshall —I have recently had under treatment a case in some respects similar to the one reported by Dr Allport

The lady, Mrs H, 32 years of age, was married eight years ago, and after two years gave birth to a son, since which she has been afflicted with a displacement—anteversion—in all probability the result of subinvolution

At times this condition has so affected her general health as to confine her to the house for weeks and months at a time At every menstrual period she was obliged to keep her bed for from three days to a week, on account of severe suffering

Five years ago she first noticed an inflamed condition of the margins of the gums, and that they were *receding from the necks of the teeth* Her dentist was consulted, and he removed a small amount of salivary calculus from about the necks of the teeth, and said that was all he could do for her, as the cause was hereditary

In June of last year (1883), was consulted by the lady with regard to the condition of her mouth She said the recession of the gums had steadily progressed, and on examination I found the gums receded to the extent of about one-eighth of an inch from the necks of the teeth, and quite uniformly about all the teeth in both jaws I found but little salivary calculus in any part of the mouth, and what was discovered was upon the roots of the teeth, and completely covered by the gums The gums were congested at the margins, and loosened from the roots of the teeth to the varying depth of a sixteenth to a fourth of an inch

Pus was found under the gums in those locations where the tartar was present

The teeth were not loose, nor sensitive to percussion, and there was no hæmorrhage except when using the tooth-brush Upon further inquiry, I ascertained the fact of the uterine displacement, and the history of the case as above stated, and that she had lately commenced treatment for that affection

I was of the opinion that there was some association between the uterine trouble and the condition of her mouth, for I could not find a sufficient local explanation to account for the manifestations in the oral cavity I therefore removed the tartar (sanguinary calculus (?)), prescribed an astringent wash for the gums, and told her we would wait the results of the uterine treatment I have seen the patient several times since her physician began the treatment, and have noticed a steady improvement in her general health, she says—March, 1884—the uterine displacement has been entirely overcome, and that menstruation is now normal The oral conditions are much improved in every respect, the congestion of the gums has entirely disappeared, no pus is to be found about the necks of the teeth, and the margins of the gums are firmly attached, but still leaving the necks of the teeth exposed This case, like that of Dr Allport's, is interesting from the fact that the oral affection was but an expression of a disease located in a remote organ

Dr Williams —I have noticed the same conditions as those mentioned by Dr Allport and by Dr Marshall, and cases are not infrequent in which diseased conditions located in the reproductive organs find expression in the oral cavity One marked case, with inflammation of the gums and discharge of pus about the necks of the teeth, occurred in a young woman married just a year, and whose mouth was in a normal condition just previous to marriage It was evidently the result of excessive venery

Dr Stellwagen —I have seen two cases of vicarious catamenial hæmorrhage from the gums and alveolus occurring after the extraction of a tooth

One was a young lady troubled with a slight ulceration of the os uteri, treatment of the ulceration resulted in the cessation of the hæmorrhage

Dr Briggs moved that the discussion on the papers be now passed, and that Dr Allport be given an opportunity to present the models of a peculiar case of irregularity, and the methods adopted for its treatment

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS.

HYPODERMIC INJECTION OF AMYL FOLLOWED BY EPILEPTIFORM CONVULSIONS — Dr Sidney Ringer (*Journal of Mental Science, Practitioner*), has noticed the occasional action of the nitrite of amyl upon the heart, and the strange effect sometimes produced upon the nervous centres He says "I have seen one case where a woman immediately after a drop dose turned deadly pale, felt very giddy, and then became partially unconscious, remaining so for ten minutes" And again "A delicate woman, after one-thirtieth of a drop, passed in a few moments into a trance-like state" In a case described by Dr Strahan, a chronic maniac aged fifty-three had suffered for several days from severe lumbago, a ten-minim dose of a 10 per cent solution of nitrite of amyl in rectified spirit was injected hypodermically "Immediately after the injection the pain disappeared He got up from the bed, and at my request stooped and touched the floor with his fingers In, as nearly as could be guessed, about a minute and a half, he suddenly became deadly pale and sank back upon the bed" Then his face, head (bald), and neck became congested, and he was strongly convulsed for about half a minute The convulsion affected the face and arms strongly, the legs slightly The teeth were ground, and the breathing was suspended In a few minutes after coming out of this fit, he was attacked by a second one, during which the heart's action became very faint He was made to inhale some chloroform, and the fits did not return The lumbago entirely disappeared This observation is interesting, as inhalations of nitrite of amyl have been recommended to check the recurrence of epileptic convulsions

ANTIPYRIN IN CHILDREN'S DISEASES As the result of numerous trials of this new anti-febrile substance on children at the Erlangen polyclinic, Professor Penzoldt (*Berliner Klinische Wochenschrift, Practitioner*) arrives at the following conclusions

1 It is to be regarded as a very suitable means for diminishing the temperature in the febrile affections of children

2 In proper doses it effects a diminution by several degrees during several hours

3 The diminution of the pulse does not always correspond to that of the temperature

4 Its influence upon the general condition of the patient is usually favorable

5 Vomiting only sometimes attends its employment, but when this persists the antipyrin must be given in an enema

6 The proper dose to begin with is as many decigrammes as the child is years old, repeated three times, at intervals of one hour If this dose does not suffice for the production of a decided effect, then it must be increased decigramme by decigramme In an enema we may give at a single dose from three to six times as many decigrammes as the child has years

7 After long use of it the child's system sometimes gets accustomed to the remedy

SURGERY.

STRETCHING THE INTERCOSTAL NERVES —Dr L von Lesser, (*Deutsche Med Wochenschr, Practitioner*) of Leipzig, has recently reported a somewhat remarkable case of intercostal neuralgia and of mastodynia treated successfully by stretching of several intercostal nerves The patient, a woman, aged 61 years, and the mother of eight children, had suffered during seven years from a feeling of compression of the thorax, very severe paroxysms of darting pains along the intercostal spaces on both sides, but more intense on the right, and neuralgic attacks in the mammæ and nipples Through the intensity of these paroxysms, which came on usually at night, she was prevented from sleeping, and her sufferings were so severe that she became very anxious that some operation should be performed which might give relief Just below the ribs, on the right side, was a fatty tumor of the size of a plum, but this was soft and free from tenderness, and clearly not the cause of the neuralgia On pressure over each of the much-atrophied mammary glands, a few drops of fluid, resembling milk, could be forced out through the nipple This fluid, which was secreted more abundantly during the paroxysms of neuralgia, presented under the microscope an abundance of oil-globules of different sizes, and a few round cells, containing oil globules As the neuralgic pains were much more severe on the right than on the left side, the operation was performed on the right intercostal nerves, from the fourth to the tenth The incision was begun in the axillary line, and carried obliquely backwards and downwards, from the upper margin of the third rib to the lower margin of the tenth rib The processes of the serratus magnus muscle having been divided, and the external intercostal muscles separated from the lower margins of the corresponding upper ribs, the seven intercostal nerves were exposed, and each forcibly stretched in a centripetal and a centrifugal direction The patient made a very speedy recovery From the date of the operation she was able to sleep soundly at night, and complained only of occasional slight "dragging pains" on the right side of the chest, and a feeling of compression over the lower intercostal spaces Up to the time of her discharge, on the eleventh day after the date of the operation, there had not been any return either of the paroxysms of pain or of the mastodynia

RAPID RECOVERY AFTER WOUND OF STOMACH AND PROTRUSION OF VISCERA —A remarkable case of recovery, after severe abdominal injury, is reported in the *Gazetta degli Ospitali*, by Dr Iginio Tansini (*Lancet*) P G , aged 46, a peasant of Lodi, was admitted into the local hospital on the 10th of August, in a state of drunkenness, with an extensive wound in the left hypochondriac region Through it protruded the stomach, the transverse colon, and a large part of the great omentum On the anterior surface of the stomach was a wound an inch and a quarter long, through which the lining of the mucous membrane bulged so as to fill it That wound was closed with two fine catgut sutures After cleaning the displaced viscera with cotton pledgets dipped in a 2½ per cent solution of carbolic acid, reduction was attempted, but the tightness of the edges prevented it As the wound reached upwards to the costal margin, it was extended an inch downwards, and the viscera replaced The parietal wound was then found to measure three and a half inches A considerable amount of blood having accumulated in the abdominal cavity, the toilette of the peritoneum was very carefully performed with carbolized gauze soaked in warm carbolized water The first pledgets brought away blood, and others were introduced amongst the coils of intestine and into the pelvis, until they came away quite clean After inserting a thick drainage-tube into the lower angle of the wound, this was closed with four deep and four superficial sutures of carbolized silk, a broad antiseptic dressing followed Progress was uninterrupted, no fever supervened In the first three days much bloody fluid was carried off by the drainage-tube, which was gradually shortened, and definitely removed the eighth day On September 5, the twenty-sixth day after admission, the patient left the hospital perfectly cured

INJECTIONS OF ETHER AND IODOFORM IN COLD ABSCESS —Professor Verneuil (*Remede Therapeutique Med Times*) obtains a rapid cure in almost all his cases of cold abscess from diseased bone, or from congestion, etc , by ethereal injections of iodoform, of the strength of one in twenty The abscess is first emptied by means of Potain's aspirator, and then receives from 100 to 300 grammes of the iodoform solution By not exceeding this quantity (*i e* , five to fifteen grammes of iodoform) no fear of accidents need be felt The liquid penetrates into all the anfractuosities and diverticula of the abscess, the ether becoming absorbed or evaporated, and the antiseptic agent being deposited uniformly on the pyogenic membrane, the action of which it modifies This simple means, so exempt from danger and so easy of application, has proved highly successful, very large abscesses having yielded to three or four injections

---

OBSTETRICS AND GYNÆCOLOGY.

LOCAL APPLICATIONS IN INTRA-UTERINE DISEASE —Dr Lombe Atthill discusses this subject quite fully (*British Medical Journal*) in his introduction to a discussion in the Section of Obstetric Medicine of the British Medical Association Speaking of oppositions encountered, he quotes from a writer in the Edinburgh *Medical Journal* in 1872, who, in reviewing his (Atthill's) first edition of Lectures on the Diseases Peculiar to Women, in which he advocated the treatment of a granular condition of the intra-uterine mucous membrane by the application to it of fuming nitric acid, said "Patients thoroughly treated in this manner will certainly have no more menorrhagia, they may be glad if they have even a uterine cavity left" He first of all points out briefly what are the conditions which demand the direct application of medical agents to the intra-uterine surface These may be briefly summed up thus All affections of local origin giving rise to profuse menstruation, metrorrhagia, or uterine catarrh, or in which hyperæsthesia of the nerves distributed over the inner surface of the uterus exists Polypi, or tumors capable of being surgically treated, are excluded, but certain forms of recurrent growths and of malignant diseases are to be included By the term "of local origin" is meant all affections depending on an unhealthy condition of the uterine walls, and of the mucous membrane lining the cavity, or of that membrane alone

In analyzing his cases, he finds that he employs carbolic acid in nearly 70 per cent , iodized phenol in about 15 per cent , and nitric acid in hardly more than 3 per cent

Borax is a mild astringent, and may be employed with advantage in cases in which uterine catarrh continues, after the application of more energetic agents has removed the urgent symptoms Dr Atthill generally employs it in the form of a saturated solution in glycerine

Iodine is, next to borax, the least active of these substances This is probably due to the fact that the uterus seems to absorb very sparingly, if at all, any agents applied to its inner surface They seem to be of value chiefly in proportion to their power of acting as a caustic

Carbolic acid When the mucous membrane of the cavity of the uterus is painted over with a solution of carbolic acid, pain, in the majority of cases, is complained of, but this dies away rapidly, unless there be some inflammatory action present, or the os internum be contracted Indeed, in many cases carbolic acid relieves pain, and while the passage of the uterine sound through the os internum, or pressure of its point against the fundus, causes pain the passage of the probe, armed with cotton saturated with a strong solution of carbolic acid, causes much less, or none at all Carbolic acid is a mild caustic, causing a superficial slough to form, which peels off in about *twenty-four hours* *Therefore, to produce a permanent* effect it must be applied at short intervals of about three or four days, and its use continued for some weeks

Iodized phenol, that is, pure iodine dissolved in carbolic acid by the aid of gentle heat, in the proportion of one part of iodine to three or four of carbolic acid, as introduced by Dr Battey, of Georgia, is one of the best, and certainly in some cases the best of all these agents

Nitric acid is the most active of all the agents we apply to the interior of the uterus Nevertheless, it causes very little pain, and its direct effects pass off quickly, for it only makes a superficial slough, which peels off in a day or two, still it requires to be used with great care, and it is necessary to use special precautions to prevent its effects from extending beyond the intended limits Thus, it should never be applied to the cavity of the uterus unless the cervical canal be protected by the introduction of a tube of vulcanite or platinum, otherwise, contraction of the cervical canal, and possibly closure of the os uteri, may follow

Iodoform in the shape of slender crayons made up with gum, which can be passed through the cervical canal into the cavity of the uterus, has been recommended in the treatment of some forms of painful menstruation Dr Atthill has not found it to be of much benefit, it may be used with advantage where there is a fœtid discharge, as in some forms of chronic endometritis occurring in elderly women

Nitrate of silver introduced by Simpson's silver uterine *porte-caustique* in ten grain quantities, dissolves slowly, and cauterizes, in a superficial manner, the mucous membrane lining the cavity and cervical canal, this peels off in a few days, and is discharged, generally with the escape of some blood Used in cases of menorrhagia depending on imperfect involution of the uterus, it often acts in a satisfactory manner, stimulating the uterus to contract, and rendering the mucous membrane much healthier, but it is a painful application, and sometimes gives rise to troublesome symptoms It possesses one advantage, that it seldom has to be applied a second time

But cases are met with in which the method of swabbing out the cavity is altogether insufficient, and in at least four distinct conditions it will be found necessary to adopt other means

1 When the uterine mucous membrane is so vascular that the introduction of the probe is followed by hæmorrhage sufficiently profuse to neutralize the effect of the caustic or astringent agent carried up by it

2 When (as when chronic endometritis exists in a very imperfectly involuted uterus) the cavity is of large size

3 When hæmorrhage occurs as the result of vascular growths, which, if removed, are rapidly reproduced, and lastly

4 *When epithelioma affects the cavity of the* uterus

To illustrate these classes Dr Atthill gives the details of cases in which he derived benefit from the injection through an intra-uterine syringe of drachm *doses of iodized phenol, diluted to one-half strength* with alcohol, and in some repeated weekly He claims that this treatment obviates the necessity of dilating the uterus, in a certain number of cases in which we have good grounds for believing that uterine hæmorrhage depends for its origin on an unhealthy condition of the mucous membrane lining the cavity of the uterus, the result of imperfect involution, but it will not obviate that necessity when the diagnosis is doubtful, next, that it will prolong life for at least a considerable period, in cases where epithelioma attacks the interior of the uterus as a primary disease, in which the only alternative is the performance of Freund's operation, thirdly, that it is a valuable supplementary treatment in cases in which, after the removal of an intra-uterine growth, the hæmorrhage continues, the mucous membrane lining the whole of the cavity being in an unhealthy condition, and lastly, that, in many cases of uterine fibroid, it enables us to tide the patient over the danger, till, the climacteric period being reached, life becomes safe. To carry out this treatment safely, only two precautions are necessary, first, the cervical canal must be patulous, so as to admit with ease the entrance of the tube of the syringe, and to permit the free egress of the fluid back into the speculum, should the cavity be too small to contain it, and, secondly, that only a very small quantity must be injected at a time, and in order that an error in this respect be impossible, the syringe used should not be capable of holding more than a drachm of fluid To sum up

1 Carbolic acid, in the proportion of one part of spirit to two of the acid, is the safest and most generally useful of all the agents employed

2 Carbolic acid should always be applied by means of a probe, round the point of which a layer of cotton is rolled, the cotton being carried up to the fundus at least twice on each occasion that the applications are made, which should be on every third or fourth day, till marked improvement takes place

3 Carbolic acid should never be injected into the uterus except when combined with iodine, in the form known as iodized phenol

4 In many cases, iodized phenol may with advantage be applied by means of a probe

5 In cases in which metrorrhagia or profuse menstruation occurs, depending on an unhealthy condition of the intra-uterine mucous membrane, the cavity being dilated and the uterus enlarged, from half a drachm to a drachm of iodized phenol may be injected with great advantage

6 In cases in which epithelioma attacks the mucous membrane of the cavity, the injection of iodized phenol promises better results than any other treatment

7 The success likely to follow the injection of iodized phenol renders the dilatation of the uterus, the use of the curette, and the subsequent application

of fuming nitric acid, less frequently necessary than has been the case hitherto

8 The injection of iodized phenol requires to be carried out with so much care, that it should never be injected except by means of a syringe which will not contain more than one drachm

9 The use of the fuming nitric acid should be limited, as a rule, to those cases in which dilatation has been practiced, and it should always be applied through a tube, inserted into the cervix uteri for the purpose of protecting the sides of that canal from the action of the acid

10 The pain produced by the application of any medical agent to the intra uterine cavity does not bear any relation to the activity of that agent, but is due to one of two causes—either to hyperæsthesia, or to narrowness of the cervical canal, especially of the os internum

MEDICINE.

PICRIC ACID AS A TEST FOR ALBUMEN AND SUGAR IN THE URINE —Dr George Johnson gives in the *Lancet* a summary of the results of the trial of this test during the past two years The objections to its use as an albumen test have been first, that it gives with peptones a precipitate not distinguishable from albumen But the peptonous precipitate, unlike the albuminous, is completely redissolved by heat much below the boiling point of water Nothing can be easier than to separate peptones from albumen if they should be combined in the same urine This may be done in two ways 1st The albumen having been coagulated by heat, the peptones, which are not affected by heat, may be separated by filtration 2d The mixed peptones and albumen having been precipitated by picric acid, the peptones are redissolved by boiling, and then separated by pouring the boiling liquid on a previously heated filter The coagulated albumen will be left on the filter, while the picrate of peptones in the filtrate will be reprecipitated on cooling

Second It has been truely stated that picric acid gives with the vegetable alkaloids a precipitate like albumen, it is, however, completely redissolved below the boiling point of water It is only when large doses of the vegetable alkaloids are introduced into the stomach, such as a five-grain dose of quinine, that enough escapes through the kidneys to give a precipitate with picric acid Cases may occur, such as those of poisoning by opium or its alkaloid, in which picric acid as a urinary test for morphine might be of practical value

Third It is a fact that picric acid, like nitric or any other acid, when added to urine, sometimes, though rarely, causes a turbidity from precipitated urates, this precipitate, however, unlike albumen, is at once and completely redissolved by heat

Fourth Picric acid is the only common test for albumen, except heat, which has no apparent effect on mucin Picric acid with acetic or citric acid causes a mucin haziness in most, if not all, normal urines One of the most conclusive proofs that picric acid does not coagulate mucin, is afforded by the following experiment Add to an albuminous urine of normal acidity an equal volume of picric acid solution, then boil, so as to ensure the complete coagulation of the albumen, and filter Add a few drops of acetic or citric acid solution to the clear filtrate, and the result will be, in a minute or two, the appearance of a slight, but perceptible, haze of mucin, which the combined influence of picric acid and heat had left in the solution, and so passable through the filter Picric acid will not coagulate albumen in an highly alkaline and ammoniacal urine, then the safest method of procedure is to acidify with acetic or citric acid, filter, and add picric acid to the filtrate The mucin coagulated by the acetic or citric acid will remain on the filter, while the albumen, if present, will pass through The mucin of normal urine must not be confounded with the morbid *mucus* from an inflamed or catarrhal mucous membrane, which is allied chemically and microscopically to pus, and, like pus, contains albumen Its presence renders the secretions visibly turbid, and the turbidity must be removed by filtration before the tests for albumen can be conveniently applied The most delicate test for a minute trace of albumen is to allow the picric acid solution to *mix*, and not merely to come in contact, with about two inches of the upper part of a long column of urine in a test tube, and then to boil the top of the liquid The more or less turbid upper layer contrasts with the clear urine below The slight haziness caused by a mere trace of albumen is always increased by heat, while the turbidity caused by urates, etc , is completely removed by heat If the urine before testing is rendered turbid by urates, these must be removed by heat before the picric acid is added, and if by mucus or other floating particles, the fluid must be cleared by filtration

The ready method of qualitative albumen and sugar testing consists in adding to about a drachm of urine in a test tube, an equal volume of picric acid solution This, when boiled, affords a certain indication of the presence or absence of albumen, then, whether albumen be present or not, add about half a drachm of liquor potassæ (P B), and boil for about half a minute Any coagulated albumen that may be present is redissolved by the alkali, and the resulting color in a non-saccharine urine is claret red If any red color is visible, there is less than two grains of sugar per ounce A solution of glucose, in the proportion of two grains to the ounce, after boiling for a few seconds with picric acid and potash, appears quite black until it is diluted with water The materials for bedside albumen and sugar testing may be carried in solid form in a pocket test case, the picric acid in powder and the potash in grain lumps

THE PATHOLOGICAL APPEARANCES IN NEW BORN CHILDREN OF DEATH BY ASPHYXIA, AND THEIR MEDICO-LEGAL SIGNIFICANCE —Dr Alfred Notiling gives (*Aerztliches Intelligenzblatt Medical Chronicle*) a report founded on post-mortem examinations of 178 children born at the ninth month, 138 between the seventh and ninth, and 142 fœtuses born alive between the fourth and seventh months The writer describes the changes characteristic of asphyxia and those due to external violence of criminal or other intent

The cases of death from asphyxia had the following special features In all the serous membranes and in the different mucous membranes, blood extravasations were found in the greater number of cases, and almost without exception sub-pericardial and sub-pleural hæmorrhages were present Extravasations were also often present in the spleen, kidneys, thymus gland, the connective tissue surrounding the pancreas, and under the scalp, epicranial aponeurosis and pericranium

In the middle ear and nasal fossæ there was almost always a dark red discoloration of the mucous membrane, and in many cases also blood was exuded

Hæmorrhages into the conjunctiva and retina, and in the form of small striations in the vocal cords, were of frequent occurrence

Extravasations into the tissue of the lungs was very rare, and blood was never found in the alveoli or bronchi unless it had come from the nose of the child or from the genital passages of the mother through aspiratory efforts

If death had not been brought about very rapidly, œdema of the lungs, larynx and nasal mucous membrane was found, and sometimes interstitial emphysema, the latter, however, not being uncommon even in case of rapid asphyxia

In the bones and muscles there were no changes, except great fullness of the blood vessels

Dr Notiling gives the following conclusions

1 Large blood extravasations in the skin are always the result of external violence

2 Effusions of blood in the muscles of the neck and in the course of the great vessels of the neck, point clearly to attempted strangulation

3 Hæmorrhages between the liver and its capsule, and in the liver substance, are always the result of external violence

4 Lesions of the peritoneal membrane, and rupture of the liver, spleen and kidneys, are due to violence They may be caused by the firm grasp of a hand round the child's body, and are not uncommon after attempts at artificial respiration

5 Hæmorrhages in the umbilical cord are very rarely caused during the act of birth, or during attempts at replacement in cases of prolapse of the cord They are almost always due to violence of some form, especially to tearing the cord

6 Thick circular blood extravasations on the head or other parts of the body may be due to either difficult labor or external violence

7 Hæmorrhages in the lips, muscles of the tongue, palate, or gullet, should raise a suspicion of violence This will be confirmed if slight wounds of the mucous membranes of the parts affected are found

8 Swelling of the lips, if not accounted for by the position of the face, during parturition, must be considered a sign of the pressure of a hand on the child's mouth

9 Hæmorrhage into the external auditory meatus and external ear was not observed in any of the cases This is always due to external violence

10 Ecchymoses in the muscles, unless the result of difficult labor, etc , are always due to violence

11 If asphyxia is caused by immersing the child in some fluid medium or in dust, this will very frequently be found in the nose, mouth, throat, stomach, or lungs

12 Blood in the trachea, bronchi, and alveoli is usually due to aspiration from the maternal passages or from the child's nose

If ecchymoses in the muscles are due to operative interference, and not to criminal acts, we must remember that the presentation of the child will probably have been abnormal, and in this case the caput succedaneum will not be on the head, but on some other part of the body , therefore the presence of a caput succedaneum on the head, with signs of external violence, will make us suspect criminal interference

CONDUCTION OF PHYSICAL SIGNS IN DISEASES OF THE LUNGS —Dr Markham Skerritt read a paper on this subject before the Medical Society of London He said (*Lancet*) that it was universally recognized that the lung tissue acted as a conducting medium for physical signs in heart disease, but it was not so fully appreciated that the physical signs of lesions of the lungs themselves might be detected at a distance from their source It might be stated (1) that physical signs due to disease of a limited portion of lung were liable to be conducted by the adjacent tissue so as to be recognized at a distance from the site of the lesion, as in front when the disease was at the back, or on the sound lung when one lung only was affected, (2) that it was therefore as important to trace to their origin the physical signs dependent upon lung disease, as it was to follow out those of a cardiac lesion Instances were adduced of the adoption by a consolidated lung of the signs of pneumothorax derived from the opposite side , the transmission to the sound side of the tubular breathing of pneumonia, the interchange of physical signs between the affected side and the unaffected in pleuritic effusion, the conduction of the physical signs of phthisis from one apex to the other, and the conveyance throughout the pulmonary region of sounds having a strictly localized origin The physical signs most liable to conduction were those of auscultation , and of these, chiefly râles and altered breathing In the localization of a conducted sign in lung disease the process was the same as in the case of a cardiac lesion In conduction a physical sign (1) retained its special quality , (2) lost in quantity in proportion to the distance from its source The readiness with which a physical sign was conducted was also of value as an indication of the state of the transmitting tissue The subject of the paper was one of considerable importance, as instances had been met with where error had resulted from a want of due appreciation of the facts adduced

In the discussion which this paper elicited, Dr Theodore Williams remembered several instances in which it had been difficult to arrive at a correct diagnosis, from physical signs being conducted away from the place at which they originated. Dr. Kingston Fowler said it was very common to find that the physical signs of a cavity at one apex of the lungs were conducted to the opposite apex.

GASTRITIS FAVOSA. A NEW DISEASE.—At a meeting of the Vienna Imperial and Royal Society of Physicians, Professor Kundrat exhibited specimens of a unique kind (*Lancet*). The case was one of favus universalis, which had given rise to an abscess of the thigh, and had terminated fatally from severe gastro-intestinal disorder, marked by an uncontrollable diarrhœa. Numerous erosions, mingled with diphtheritic swellings, were found in the mucous membrane of the stomach, and the intestines contained some foul putrescent masses, and much mucus. Professor Kundrat at once declared the diphtheritic swellings to be due to the favus fungus, a view which was confirmed on microscopic examination. This is the first recorded instance in which the mucorineæ have been the cause of death, as it is the first of favus of the stomach and intestines. Indeed, the naked-eye appearance of the tumors in the stomach closely resembled the favus cups on the skin, and the fact that but little of the fungus was found in the intestine was explained by Professor Kaposi by their having undergone putrefaction in the bowel. The patient had previously been shown to the Society by Professor Kaposi as a rare instance of favus which covered the entire body, affecting even the finger-nails (attributed to his habit of scratching himself constantly). Favus of the stomach is as unknown a condition in animals as it is in man; at any rate, Professor Croker, of the Vienna Hospital for Animals, stated that it never occurred in cats, although these animals frequently eat rats infested with the fungus. Professor Bamberger suggested that in this case the gastric mucosa was in an unhealthy condition at the time of infection, thereby affording a favorable nidus for the growth of the fungus. It must be borne in mind that the mucorineæ, unlike the schizomycetes, can thrive in acid liquids, and may therefore grow with impunity in the stomach. The case is of great importance, as showing that if they do gain access to the interior of the body, these fungi may be a source of danger and lead to a fatal result, thereby disproving the usually accepted notion of their harmless character.

ON THE SECRETION OF BILE.—Dr. Baldi has recently undertaken (*Lancet*) a series of experiments on the process of secretion of the bile, in the laboratory of M. Luciani, of Florence, in which he has endeavored to ascertain whether it takes place in a uniform manner in accordance with the presence or absence of food in the alimentary canal, and whether it varies materially with the nature of the food.

The results are given in the third volume of the *Archives Italiennes de Biologie*. A biliary fistula was first made, the ductus communis choledochus being ligatured so that no bile entered the duodenum. Dr. Baldi found that there was a singular irregularity in the quantity of the secretion formed, distinguishing the functions of the liver from all other digestive secreting organs. Not only was there great variation in the absolute quantity secreted, but the composition of the bile differed remarkably at different periods after a meal. Speaking broadly, in an animal that has been supplied with food, there is an augmentation in the total quantity of bile secreted in the course of some hours, as compared with the quantity secreted in the same time by the animal when fasting. It is not possible, however, to fix the time at which the secretion of bile after food is at its maximum; indeed, it is even possible that the maximum may be attained during some one hour when the animal is fasting.

Different kinds of foods, starches, proteids, fats, and mixed foods, have no appreciable effect on the quantity or quality of the bile. If we consider, in addition, that, unlike the other secretions which are poured into the intestinal tract, the bile continues to be secreted in prolonged fasting, as has been demonstrated by various experiments, we shall be led to the conclusion that this fluid, from a physiological point of view, has more analogy with urine than with the other digestive fluids. In a second series of researches, in which the effects of reputed cholagogue drugs were investigated, Dr. Baldi is not in accord with either Röhrig or with Rutherford. Rohrig found that colocynth was the most active cholagogue; then, in succession, jalap, aloes, senna, and rhubarb. Rutherford considered the order to be—podophyllin, rhubarb, aloes, colocynth, senna, and other drugs. Baldi experimented with podophyllin, rhubarb, jalap, sodium phosphate, pilocarpine, and Carlsbad water, and, from his results, feels inclined to doubt altogether the cholagogue value of all these substances. He admits, however, that the presence of a biliary fistula seriously interferes with the action of remedies. Dr. Baldi undertook still another series of experiments, to determine whether bile injected into the blood was excreted by the liver. The animal employed was the dog. The bile injected was that of the ox deprived of mucus. Dog bile is brown, ox bile green. Almost immediately after the injection of ox bile the color of the bile secreted by the dog became green.

RESORCIN IN THE TREATMENT OF POISONED WOUNDS.—Justus Audier relates a series of cases (*Monatshefte in praktische Dermatologie*, *Edin. Med. Jour.*) where severe local inflammation, accompanied in some with lymphangitis, and general constitutional disturbance followed wounds on various parts of the body. Some of these were dissection wounds, others poisoned by the contamination of chemical agents. In all the instances narrated the inflammation subsided, and the pain and constitutional symptoms ceased within a few hours after the application of a resorcin-vaseline salve. The strength of this is only given in one case, equal parts of each; in the others the percentage of resorcin is said to have been high. That absorption of the resorcin took place was shown by the urine assuming a brownish green color. The details of the cases are given.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 65 RANDOLPH STREET,
CHICAGO ILLINOIS

SATURDAY, FEBRUARY 7, 1885

IS ABILITY to tolerate large doses of a medicine in any given disease without manifesting its ordinary effects, evidence that such medicine is of remedial value in the treatment of the disease?

We have been induced to ask this question by the frequent appearance of articles in medical journals, and of reported cases in papers read before medical societies, in which very large doses of known active medicinal agents have been given in certain acute general diseases without inducing any correspondingly exaggerated effects And this apparent tolerance of the remedy has generally been mentioned as one of the evidences that it was specially indicated in the treatment of the disease The most recent illustrations of this have been in reference to the use of alcohol in the form of whiskey or brandy, and of mercurials in the treatment of diphtheria To the extravagant use of the latter, particularly in the form of calomel, we had occasion to allude in these columns , few months since Since that time, however, there has appeared in this journal the paper on diphtheria read in the Section of Diseases of Children by Dr Brown, with the discussion thereon a the report of cases of the disease treated with large doses of whisky in the proceedings of a recent meeting of the Chicago Medical Society, and the paper of Dr Batten, in the present number, in which he speaks of giving it freely in all stages of the disease Some of these writers, and several of those who took part in the discussions, mention the giving of from 130 c c, to 260 cc, or four to eight ounces of whisky or brandy per day, generally mixed with milk and sugar, to children suffering with diphtheria between three and ten years of age, for several days in succession It is well known that such quantities given to children of the same ages in health, generally produce, first, intoxication and then profound anæsthesia or unconsciousness, and in some instances on record, death has ensued But the almost uniform testimony is, that in the cases of diphtheria, no symptoms of intoxication follow the administration of the alcohol, and this is alluded to as evidence that the remedy is both strongly indicated and well borne Is this, however, a necessary or justifiable inference from the premises? Is tolerance of unusually large doses, or apparent insensibility to the ordinary effects of any remedy during the progress of an acute disease, proper evidence that such remedy is either indicated or acting beneficially? On the contrary, is it not rather strong proof that the morbid conditions present have so diminished or perverted the nervous sensibilities and molecular movements that the remedy is neither taken up with facility nor its presence responded to as in health, and consequently that it is not capable of acting as an efficient remedy while such morbid conditions continue?

It is hardly three decades of time since the same reasoning was applied to the use of opiates and anæsthetics in the treatment of tetanus, delirium tremens, etc We were pointed to the very large quantities of those powerful agents that patients laboring under the diseases just named usually tolerated without marked effect, as evidence of the propriety of their use And not a few were dosed so actively that when the morbid conditions begin to decline, the quantity of medicine in the system speedily developed profound stupor and sometimes death Such results are liable to occur from the indiscriminate administration of any active drug in large doses frequently repeated during the progress of all acute self-limited diseases And nothing is easier than to deceive ourselves in regard to the benefits of medicine unless we carefully note all the circumstances connected with the natural history of the disease we may have under treatment For instance, it is well known that diphtheria has its stage of development, during which the membranous exudation and tumefaction of the glands and tissues involved are increasing, which may last from two to four days, the stage of maturity, during which the exudation disintegrates, and the inflamed tissues begin to undergo resolution, ulceration, or gangrene, according to the grade of severity, which lasts from three to five days, and the stage of repair or convalescence that may occupy from one to three weeks. It is easy to see that a physician coming to his patient near the end of the first stage for the first time (which is often the case) and prescribing some particular remedy, might find the next day a marked change for the better indicated by less fever and loosening or disintegration of the membrane, and what more natural than to conclude that his remedies had produced the change when in truth they had nothing to do with it, or might have been even injurious in other directions?

Again, it is known to all who have given attention to the subject that diphtheria, like most other zymotic or acute infectious diseases, varies greatly in its severity in different seasons and in different families and localities in the same season, and also pretty uniformly displays its highest degree of malignancy at the commencement of an epidemic outbreak.

In consequence of these natural differences the ratio of deaths vary greatly under precisely the same treatment, or without any medication whatever. Thus thirty years since, at the beginning of one of the most extensive epidemics of diphtheria in this country, in a little town in New England, of the first fourteen cases thirteen died. Before the same general epidemic period was passed, during a well-marked prevalence of the disease in a neighborhood near Milwaukee, Dr. Wells reported 133 cases coming under his observation in one season, only four of whom died, and three of the four were in the first family attacked. If Dr. Wells had reported the first seven cases separately, as did Dr. Chandler at a recent meeting of the Chicago Medical Society, like the latter he would have had three deaths in the first seven cases, and only one in the remaining 126, and that without any use of whisky or brandy for any of them. Dr. Batten, whose article is in the present number of the JOURNAL, and who recommends the use of alcoholic remedies in all stages of the disease, claims 80 per cent. of recoveries, *i. e.*, one death in every five cases, which is certainly a high ratio of mortality for the disease as it usually occurs from year to year in any given community. We call attention to the foregoing sources of fallacy in estimating the effects of remedies because we are satisfied that the present popular tendency to use large doses of alcoholic remedies in diphtheria is productive of positive detriment to the patients.

ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.—The official notice of the Permanent Secretary for the thirty-sixth annual session of the National Association, to be held in New Orleans, La., commencing on Tuesday morning, April 28, 1885, will be found in the present number of this journal under the head of Miscellaneous Matters. Let all readers interested read the notice carefully, as it gives the ratio of representation by delegates from State and local medical societies, the officers of Sections, the by-laws relating to presentation of papers, and some proposed amendments to the constitution and by-laws.

As the great International Exposition will continue open until the 1st of June, and the railroad lines promise liberal reductions of fare over the more important routes to New Orleans, the circumstances are favorable for a full and important meeting.

ANOTHER UNIVERSITY OF PHILADELPHIA DIPLOMA HEARD FROM.—*The Australasian Med. Gazette*, Oct. 15, 1884, contains a letter from a writer who signs himself V. E. Herbert, M. D., who complains that the Medical Board of New South Wales has refused to register his diploma for the degree of Doctor of Medicine granted by the University of Philadelphia, U. S., "this University being one whose degrees are recognized and well thought of in that country." The writer moreover declares himself to have been for twelve months an assistant surgeon in the American navy. He goes on to say: "I know full well that American diplomas are deservedly unpopular, because so many of them are obtained almost without study. But this was not my case." He also claims a license from the School of Medicine of New York. The editor, in his comments upon the letter, does not appear to have the slightest suspicion that there may be any irregularity in the character of the diploma itself.

THE ETIOLOGY OF THE OPHTHALMIA OF NEW-BORN INFANTS.—Zweifel (*Arch. für Gynäk. Rev. Mensuelle des Maladies de l'Enfance*) asks if the ophthalmia of new-born infants may be produced by the normal utero-vaginal discharge (lochiæ), by the secretion furnished from catarrhal inflammation of these parts (leucorrhœa), or by a specific infectious agent (blennorrhagia). Neisser has described a special diplococcus gonorrhoæic which may be the microbe of blennorrhagia and which may be the cause of ophthalmia in the newly-born.

Zweifel has collected by the use of the pipette some of the lochiæ from the vaginæ of newly delivered women who were perfectly healthy, which under the microscope did not give any traces of the gonococcus, and has inoculated this liquid into the conjunctive cul-de-sac of six new-born infants, but there followed no trace of inflammation or suppuration, and he arrives at the conclusion that in order to have purulent ophthalmia in a new-born child there must be blennorrhagic inflammation of the genitals of the woman.

SOCIETY PROCEEDINGS.

CHICAGO GYNÆCOLOGICAL SOCIETY.

Regular meeting of the Chicago Gynæcological Society, Friday evening, January 16 1885 The President, Dr H P Merriman, in the chair

Dr E C Dudley read a paper on an interesting and unusual case of double ovariotomy The specimens were subsequently exhibited

The patient, 18 years old, unmarried, came to Mercy Hospital, about 18 months ago, to consult Dr Dudley about marked abdominal enlargement The diagnosis of monocystic tumor of the parovarium or broad ligament was made The cyst was aspirated, and two gallons of fluid were removed This fluid possessed the following characters Sp Gr , 1000 5, neutral reaction , limpid as water , odorless , colorless, on microscopical examination no morphological constituents were detected , on chemical examination certain mineral salts were found, but no albumen

The patient experienced so much relief after aspiration, that she left the hospital with the impression she was permanently restored to health

About three months ago she visited Dr Dudley at his office It was found the cyst was partially refilled An operation was determined upon

The preparatory treatment of the patient, — apart from tonics, the most nutritious of foods, frequent baths, and finally a Turkish bath immediately preceding the day of operation, — consisted in the exhibition of remedies, designed to increase the tonicity of the muscular coats of the intestines, and to expel all the gases For this purpose the patient was given, two or three times daily, a mixture of columbo, rhubarb, and compound tincture of cardamom In a case, operated upon early in the autumn, Dr Dudley had experienced much difficulty in the management of the intestines, which were distended with gas In this case, subjected to the preparatory treatment just detailed, absolutely no difficulty in that direction was encountered

The *mons veneris* was shaved, the vagina irrigated immediately before operation

The details of rigidly antiseptic surgery were observed with reference to the operating room, instruments, operator and assistants

On October 29, Dr Dudley, asisted by Dr W W Jaggard, Dr R W Bishop, and Dr W E Casselberry, performed ovariotomy, and removed both ovaries and tubes, together with a large monocyst of the left broad ligament The pedicle of the large cyst was very vascular and, after transfixion with the passage of the ligature around each half, the operator was compelled to ligature *en masse* below the point of transfixion The pedicle was afterwards seared above the Baker-Brown clamp, with Paquelin's thermo cautery Ether was employed as the anæsthetic

The patient reacted well At noon, two hours after operation, temperature 100 7°, pulse 150 respiration 20 She complained of nausea Evening temperature 100 8°, pulse 115, respiration 20 Nausea continues , no tympanites

Oct 30, morning, temperature 100 4° , pulse 112 , respiration 20 Evening, temperature 101°, pulse 124, respiration 20 Throughout the day the patient moaned and tossed, complained of nausea, vomited incessantly A peculiar, talkative delirium ensued Morphia and atropine were given to suppress vomiting, discontinued the atropine, fearing its cerebral action Hot water, as suggested by Mr Keith, was tried, with hope of checking nausea and vomiting, without success The deodorized tincture of opium was substituted for morphia The talkative delirium, nausea and vomiting continued unabated The patient retained only a little ice water at long intervals

Oct 31, morning, temperature 99 8° , pulse 110 , respiration 20 Evening, temperature 99 8° , pulse 110 , respiration 20 Nervous symptoms greatly exaggerated , nausea and vomiting unabated , pain in the abdomen, complained of at intervals Cordeia was substituted for the other opiates Small quantities of milk and lime water, at intervals, were exhibited The patient remained in the same condition talkative delirium, no sleep, nausea and vomiting, pain in the abdomen, at intervals, no tympanites

Nov 1, morning and evening, temperature 99 7° , pulse 106, respiration 20 Talkative delirium, nausea, vomiting of bile,—the “mouth-filling” of Mr Keith,— abdominal pain , no tympanites She commenced to menstruate, or, at least, blood began to escape from the vagina

Nov 2, morning, temperature 98 8° , pulse 114, respiration 18 Evening, temperature 98 6° , pulse 135 , respiration 21 Nervous symptoms more distressing , nausea and vomiting continuing , patient becoming emaciated , face taking on a pinched, anxious expression Valentine's beef juice exhibited , mustard to epigastrium , strychnia, in small doses , champagne , bisulphate of quinine, *per rectum*

Nov 3, morning, 8 A M , temperature 101°, pulse 130 - 10 A M , temperature 101 2°, pulse 160 10 30 A M , temperature 101 6°, pulse 178 Persistence of wild, talkative delirium, nausea, vomiting, abdominal pain The pulse, while very rapid, was not the feeble pulse of collapse

In a consultation with Dr W H Byford on the previous day, it was decided that the patient was dying of exhaustion Dr Byford was averse to reopening the abdominal incision

Dr Dudley had one case of peritonitis following perforation of the posterior uterine wall, in Mercy Hospital, that died of septic poisoning, although the temperature did not rise above 100°

With the aid of Dr R W Bishop, Dr Dudley etherized the patient, removed four or five stitches from the lower end of the abdominal incision, and inspected the cavity of the abdomen The peritoneum was injected , no lymph was noticed, no gas in the intestines The pedicles were not covered with lymph A disinfected sponge on a holder was passed into the cul-de-sac of Douglas , about one-half of a fluid ounce of bloody serum was removed This red stained fluid was odorless, it was not further examined Feeling no good had been accomplished, the incision was reunited

This operation was performed at 10 30 A M Temperature at 12 M 101°, pulse 150, temperature at 2 P M 100°, pulse 144, temperature at 3 P M 100° pulse 135 temperature at 7 P M 100°, pulse 140 jactitation wild delirium, nausea and vomiting, pain in the region of the cœliac axis, no tympanites Rectal alimentation

Nov 4, morning temperature 100°, pulse 135–150 Whisky, beef tea and milk at regular intervals bisulphate of quinia *per rectum* persistence of the symptoms before detailed In the afternoon the tongue was dry, cracked, ready to bleed decidedly less nausea and vomiting The nurse was directed to give the patient an enema of soap and water, with extract of ox gall One quart of this mixture was injected into the bowel No evacuation of the contents of the rectum following, a tube was introduced, which was followed by that classical sign, the audible passage of flatus Mr Keith says that if the intestines have sufficient muscular energy to expel flatus, the prognosis becomes more favorable It is probable a reversed peristalsis occurred, and the injection was entirely absorbed One hour afterwards the tongue became moist

Evening temperature 101°, pulse 135 Acting on the suggestion from the enema, one quart of strong beef tea was introduced into the bowel

Nov 5, patient evidently in better condition temperature, morning and evening, 98–99° pulse 120–130° One quart of strong beef juice was exhibited *per rectum*, and carried well up into the bowel About three-fourths of this quantity was retained Slight nausea and vomiting Bowels were moved spontaneously, with evacuation of a large quantity of dark, tarry, fœtid fæces The sutures, originally inserted, were removed

Nov 6, morning, temperature 98 5° pulse 90 evening, temperature 98 1° pulse 115 Bowels were again moved spontaneously with evacuation of dark, tarry, fœtid fæces All the symptoms of the patient assuming a favorable character Beef tea, whisky, quinine, and nutrient enemata continued From this time on, the patient made an uninterrupted recovery At the end of two weeks she was removed to St Luke's Hospital She is now in good health and pursuing her usual avocation In conclusion Dr Dudley called attention to the three following subjects, and requested that the discussion should be more particularly limited to their consideration

1 *Preparatory Treatment of the Intestinal Tract* Is it possible to render the intestines manageable during an operation in the abdominal cavity by any dietetic or medical agencies? The escape of the intestines without the abdominal parities was a very distressing complication The shock of the operation was increased, large vascular areas were rapidly cooled, notwithstanding the fact that they might be enveloped in warm, disinfected fabrics It was not always easy to return the intestines to the cavity of the abdomen, and even then, there was danger of strangulation He was of the opinion that in the case reported, the rhubarb columbo and cardamom were active in restoring tonicity to the muscular coats, and in the expulsion of flatus

2 *The Retention of Enemata* It was a matter of surprise to him that one quart of fluid exhibited *per rectum*, on three successive days should be retained He supposed that the liquid portions of the injections were absorbed at once, in consequence of the state of the tissues, resulting from exhaustion The return of the tongue to a moist condition within a very short space of time immediately following the injection was evidence in favor of this explanation

3 *The Reopening of the Abdominal Incision* Had it done any good? What produced the excessive nervousness? What was the cause of the nausea and vomiting?

The problem was an intricate one It had been asserted that a very tight ligature around the pedicle can act as a reflex irritant The sutures in the abdominal incision are sufficient at times, to produce various obscure reflex symptoms He had one case, —his first case —in which uncontrollable vomiting yielded immediately upon the withdrawal of a rubber drainage-tube

It may have been that the case reported was just on the eve of recovery when the abdomen was opened

The fluid removed was small in quantity, and without odor The peritonæum however, can secrete with wonderful rapidity and then absorb the secretion He had not examined the fluid microscopically or chemically He had dusted into the cul-de-sac a small quantity of iodoform Whether *post hoc* or *propter hoc*, the patient recovered

If it was a case of exhaustion, the beef, milk and whiskey deserved the credit If a case of sepsis, the reopening of the incision was the potent factor In answer to a question by Dr Sawyer, Dr Dudley said that although the delirium of the patient was attended with visions of snakes alcohol was out of the question, from his own knowledge of the habits of the patient In answer to Dr Merriman's question as to the preparation of the ligatures, Dr Dudley said that silk thread was used exclusively for sutures and ligatures This silk thread was boiled for ten minutes in 95 per cent sol carbolic acid then for thirty minutes in 5 per cent sol carbolic acid finally, it was deposited in a solution of the bichloride of mercury, 1 to 4,000

Dr Dudley then exhibited the specimens The right ovary was slightly enlarged and in the commencing stage of cystic degeneration A cyst, about the size of a hickory-nut was found in the right broad ligament The left ovary was converted into a mass of fibrous tissue about the size and shape of a kidney Springing from the left parovarium or from the left broad ligament was the large monocyst. to which allusion has been made This cyst. at the time of operation, contained about forty pounds of fluid

DISCUSSION

Dr Henry T Byford thought that the reopening of the abdominal incision was unnecessary Relief could not have come from the removal of such a small quantity of fluid as one-half fluid ounce The improvement immediately following the operation was probably due to the stimulant effect of the ether The delirium seemed to him to be that of alcohol or cerebral anæmia He did not think that the symptoms of nausea and vomiting could be explained by any local irritant, such as ligatures, or sutures It was a case of exhaustion, cured by the judicious exhibition of beef, whiskey and milk

Dr Edward Warren Sawyer said the patient owed her life to the persistent bravery of the operator and congratulated him upon his success He was surprised to hear that no albumen was detected in the aspirated fluid Friedrichs says albumen is always present in such cases, but absent in echinococcus cysts

Dr Flavius M Wilder said that egg albumen in water was frequently tolerated by the stomach when other matters were rejected

Dr W W Jaggard thought the secretory and resorptive functions of the peritonæum were matters of positive knowledge Dr Anton Wolfler, in a recent paper, has taken substantially Dr Dudley's position It is quite possible that the one half fluid ounce of blood serum, found in the cul-de-sac, represented the ultimate stage of resorption of a much larger quantity of fluid

One-half fluid ounce of fluid, however, may contain enough sepsin or sufficient bacteria to produce the most fatal pyæmia There is no quantitative relationship in regard to the virulency of certain poisons

The mere reopening of the abdominal incision seems to act, under certain conditions, in a favorable manner The reason is unknown It is an empirical fact, acknowledged by a number of leading surgeons He thought Dr Dudley deserved great credit for his action in taking up the suggestions of numerous operators, when he knew positively no foreign body was contained within the abdominal cavity

Dr W E Casselberry wished to emphasize the importance of the preparatory treatment of the intestinal tract He had been present at both of the operations to which Dr Dudley had referred, and was struck by the difference in the behavior of the intestines The mixture employed by Dr Dudley resembled a favorite formula of the late Dr Geo B Wood This formula was advised for the expulsion of flatus, and restoration of tone to the intestinal muscular walls

Dr D T Nelson said it was highly important to avoid the use of opium when it was possible The less opium, in general terms, the less tendency to vomiting As to the pedicle, he entertained grave doubts as to the propriety of passing the ligature *en masse* In strangulated hernia, uncontrollable vomiting frequently resulted from the inclusion of omentum in the ligature Would it not be better to open the pedicle and pass a ligature around each vessel separately? He thought Bantock, Thornton and Spencer Wells advised the same treatment as in the securing of the vessels in an amputated leg

Dr Sawyer said he had seen Dr John E Owens remove a testicle, following the passage of the ligature around the cord, uncontrollable vomiting occurred

The reopening of the abdominal incision was looked upon with too much fear He had been present at an operation in which all the blood had not been removed from the cul de-sac, the patient died of septicæmia At the autopsy, Douglas's pouch was filled with blood, an operation might have saved life Another case in point, was one of normal double ovariotomy After the operation the patient sank rapidly The operator concluded the patient was suffering from internal hæmorrhage Twelve hours later the abdominal incision was reopened, and after two hours search the bleeding vessels were secured The patient recovered

Dr H P Merriman endorsed Dr Dudley's reopening of the abdominal incision in the case presented

In regard to the preparatory treatment of the intestinal tract, he was not certain that the exhibition of columbo, rhubarb and cardamon, had produced the favorable result in the one case, nor that the neglect of preparatory treatment was operative in the troublesome condition in the other He did not think the opium was the cause of vomiting, since the nausea disappeared while the patient was still under the influence of opiates He did not think the ligature *en masse* or the clamp could be replaced by the methods suggested by Dr Nelson The danger from hæmorrhage was too great It was an admirable subject for study If the pedicle was completely destroyed, the danger of pinching nerve filaments would be less The quantity of fluid removed after reopening the incision, was not sufficient to account for the improvement in symptoms

Dr Nelson referred to the compression forceps, and ligature placed above, as designed to obviate the inclusion of nerves still sensitive

Dr Dudley closed the discussion The mere opening of the abdomen seemed to act in a remarkable manner under certain conditions Tubercle of the peritonæum, papilloma of the omentum were pathological states which had been influenced favorably by the procedure

Cocculus Indicus is supposed to have the same effect as the mixture exhibited to prepare the intestinal tract

It was not necessary that a discharge should have a foul odor or be large in quantity in order to be capable of producing pyæmia

The Society adjourned to meet at the Palmer House, as the guests of Dr Sawyer and Dr Jaggard, on Friday evening, Feb 20, 1885

Dr H T Byford will read a paper on "The Functions of the Membranes in Labor"

The inaugural thesis of Dr Chas Caldwell, on "Two Interesting Cases in Obstetrics," will be discussed

2330 Indiana Ave , Jan 19, 1885

FOREIGN CORRESPONDENCE.

LONDON LETTER.

LONDON, Jan 7, 1885

A most valuable and important report by the medical officer of the local government board has just been issued as a supplement to the report of the board itself Dr Buchanan records the increasing recognition which, under Sir Charles Dilke, the medical staff of the board receives, and says that quite 6,000 questions were referred to it in 1883 His report tells the year's history of vaccination work, of medical inquiries into epidemics, and the communication of diseases by milk, and with a glance at the cholera, passes on to the important scientific investigations made during the year into the chemistry of putrefaction, as well as into questions of infection and disinfection, and the organisms which produce disease The anti-vaccinationists have not made much diminution in the use of the great prophylactic against small-pox The latest returns are for 1881, but they show that only 3 8 per cent, or, including postponed cases, 4 5 per cent of the children whose births were registered in that year are unaccounted for as regards vaccination Allowing for those who died during the period in which they may lawfully remain unvaccinated, the numbers vaccinated were twenty times those which remained unvaccinated Yet, among the unvaccinated children the deaths from small-pox were ten times as numerous as they were among the twenty-fold larger number of vaccinated children The rate of mortality from small-pox in the two classes was as 200 is to 1 Of the chances of the spread of cholera to England, Dr Buchanan does not venture to express an opinion He points out, however, that its presence in the Mediterranean is a much less formidable threat for England than an outbreak in the Baltic, though with the increased traffic between Asia and Europe this difference may be obliterated

There are reports, too, on local outbreaks of disease which give evidence of the watchfulness of the local government board over the public health If an outbreak occurs in a school, a village, or a town street, its origin is carefully traced, every circumstance connected with it is duly noted, and all the facts, with the practical inferences to be drawn from them, are set forth and acted upon So complete a system for the staying of local epidemics has never before been set up in any part of the world The progress made during the year in the use and application of disinfectants to disease is indicated in special and detailed reports by Dr Burdon Sanderson, Dr Klein and McDowdeswell One of the most striking points in the report of the board for 1883-84 is the list of towns in which compulsory notification of infectious disease has been adopted At the beginning of 1884 there were thirty-four towns, with an aggregate population of 2,653,565, in which it is the duty of the householder or of the medical attendant, or of both together, to notify the local authority of any case of infectious disease which occurs under their control The power to require this notification is given to the municipal authorities by local acts, and was first acquired in 1877 by the corporation of Bolton In the next year the corporations of Nottingham, Burton-on Trent, and Jarrow, received the same power Every year since has added to the list, which comprises sixteen Lancashire towns Last year the corporations of Brighton, Chester, Croydon and Shrewsbury have included the same provision in local acts, so that it now extends to 38 towns, and covers more than one-eighth of the total population outside of London The system works well It is administered by municipal corporations whose members and officials are personally known, and have the confidence of their constituencies It by no means follows even in the most infectious cases, that removal follows notification The local authority acts with due consideration for the feelings of families, and the precautions taken are as valuable for the home in which the outbreak has occurred as for the community The success of the scheme depends entirely on the spirit in which it is carried out In London no one would submit to the interference in his domestic concerns of parish officials, of whom he knew nothing and whose judgment and consideration he could not trust This effective mode of checking the spread of infectious disease must therefore wait for its application to London till there is a municipality to apply it

An event of great importance in the hospital world has taken place in the opening of the Miller Memorial Hospital at Greenwich, by the Lord Mayor Its chief importance lies in its being the first hospital with circular wards in operation in the world Every precaution has been taken in the selection of the medical and surgical staff to make it a good school for students to gain knowledge of their profession, it will thus act as a boon to many who now find the greatest difficulty in getting efficient training in the London hospitals on account of the great number of men attending them

Dr Price, the Welsh Druid, has again made himself conspicuous by his cremationist eccentricities One night he cremated a bull thirteen years old, called Morgan Apis, to which the Druid was peculiarly attached The proceedings lasted nine hours, and the field where the cremation was carried out was crowded with spectators Dr Price some years ago used to attend the annual meetings of the British Medical Association attired in a peculiar dress, supposed to represent the robes worn by the Druids at an early period of English history

Mr Morgan Hughes of the Westminster Hospital, calls attention to the value of cocaine in toothache He used a 10 per cent solution of the hydrochlorate of cocaine in oil of cloves, applied freely by means of cotton wool both to the pulp cavity and to the gums Its application at once stopped the pain, and in extracting the tooth the patient did not feel the application of the forceps until the tooth left the socket Mr Hughes thinks dentists will find it useful in the preparation of cavities prior to filling them

It is stated that there are seventeen quinine factories in the world, six in Germany, two in Italy, three in France, two in England, and four in the United States The annual total production of sulphate of quinine by these seventeen factories is said to be, as nearly as possible, 4,250,000 ounces

Dr Murray Lindsay, the Medical Superintendent of Mickhover Asylum near Derby, was attacked recently by one of the patients with a chisel Three wounds were inflicted, one under the fifth rib being of a somewhat serious nature

Last month an anti-vaccination demonstration of an extraordinary kind was made in London An open hearse with a child's coffin, preceded by a band in a brake playing the dead march in "Saul," followed by a number of vehicles displaying placards, setting forth the object of the demonstrators, passed through the principal streets, attracting great attention

It may not be generally known that the popular word "microbe" is said to have been coined by M Charles Sedillot, of Strassburg, and that it was first used in a paper on M Pasteur's discoveries before the French Academy of Science in 1878 In replying to M Sedillot, M Pasteur used the word twice, after which it was generally adopted by scientific men The *Medical Record*, however, doubts the accuracy of this statement, and says it was not M Sedillot, in 1878, but Prof Pacini who first used it, in 1854, while speaking of a micro organism of cholera

Sir Lyon Playfair will be the President of the British Association at Aberdeen in 1885 This selection of President has given the greatest satisfaction

G O M

PARIS LETTER.

PARIS, Jan 9, 1885

In his thesis for the doctorate, "On the Conditions for Surgical Intervention in the External Localizations of Tuberculosis," Dr Coudray formulates certain rules which the surgeon might attend to with advantage to himself as well as to his patient In a general way, the author states that external tuberculoses necessitate intervention only in such cases as do not present a spontaneous tendency to cure The natural tendency to cure, which is frequent in a certain class of patients, constitutes, on the contrary, the exception with those who frequent the hospitals The formation of secondary foci, consecutive to operations, may be considered a rare circumstance, if not exceptional The doctrine of auto inoculation, according to the same author, is no argument against intervention The rule by which a tuberculous lesion should be removed as soon as it becomes a cause of wasting debility, is, according to Dr Coudray, a dangerous one It seems to him preferable to say that the lesion should be removed *before* it becomes a source of weakness He admits, however, that the indications concerning the nature of the intervention sometimes present the greatest difficulty as regards tuberculous osteo arthrites and certain other forms of osteitis Dr Coudray does not believe in the efficacy of partial operations, particularly near the joints, but, as he states, it is impossible to lay down even general rules on this point, as the surgeon must be guided by circumstances The contra-indications of surgical interference reside in the predominance of the gravity of visceral lesions over the external localizations

The JOURNAL of the 6th instant contains an editorial on, "*The Absence of Free Hydrochloric Acid in Stomachs Dilated from Carcinomatous Stenosis of the Pylorus*" It may be interesting to give here an extract of a paper read before the Medical Society of Hospitals by Dr Dujardin-Beaumetz, on the same subject According to this physician, this sign is of little or no value as a means of diagnosis, as according to his experience he has found that in some cases of cancer of the stomach the gastric juice was acid whilst in other cases where there was no cancer the gastric juice was neutral This of course was verified at the necropsy of the patients

It is well known that certain physiologists, guided by the different results produced by electricity on the dead body and on living animals, have considered faradisation to be one of the best means for distinguishing real from apparent death In a paper by Dr Bochefontaine, which was communicated by Professor Richet to the Academy of Sciences, the author endeavors to overthrow this assertion, and advances the following proof in support of his views He proposes the question an animal being submitted to a faradic current in a limited region, in what conditions would the contact of the fingers with another part of the body produce a shock on the experimenter? Experiments practiced successively on living and on dead animals, have produced variable results, even in the course of the same experiment The author therefore concludes that it would be imprudent to found, on such phenomena as these, a method of establishing the difference between real and apparent death, until some more scientific explanation can be given of this particularity

The doctor was induced to try the above experiment, in order to find out some immediate sign of certain death, instead of having to wait for the setting in of putrefaction, which, up to now, is the only positive sign known by which certain death is distinguishable from apparent death, for during the late cholera epidemic several patients afflicted with the disease were found in that state, and it is to be feared that some were actually buried alive, as those dying from the disease were almost immediately interred, and this is not to be wondered at, as cholera patients have a cadaverous appearance A case in point was reported to have occurred at Genoa, in the person of a Dr Canepa, one of the leading physicians of that town The report states that the doctor was seized with the cholera in the morning, and the disease ran its course so rapidly that in a few hours the patient seemed to have ceased to exist The usual formalities for a funeral were gone through, but on bringing the coffin to his room, he presented himself at the door and inquired in a ghastly tone why he had been left for so long a time without his tea and rum The undertaker and his men were so terrified that they at once disappeared A doctor was immediately called in, and, in consultation with other physicians, practiced the hypodermic injection of water saturated with chloride of sodium (hypodermoclysis, as the Italian physicians term the operation). This is simply an extension of Pacini's recommendation, practiced also by M. Duchaussoy, of Paris, and fully described in the "Report on the results of the different methods of treatment pursued in Epidemic Cholera, addressed to the President of the General Board of Health" (page 13, London 1855). In this report Pacini says: "It is clear that the injection of salt water into the veins produces immediate reaction, but it is easy to see that the said reaction cannot be maintained so long as the intestinal transudation lasts. Every one will admit that the primary cure for a leaking wine barrel is not to keep filling it, but to make it tight; all the more is this the case in the human subject, where the vascular system has the power of refilling itself the moment the overflow ceases. So long as the patient is capable of swallowing astringent and antiseptic drinks, I do not believe the physician is authorized to practice those injections, since, besides being attended with risks, they are not absolutely required until the stage of apparent death; at least, in bodies presumed to be dead which present some return of warmth or some movement. The use of astringent and antiseptic beverages may be resorted to when reanimation manifests itself." The operation, however, of hypodermoclysis practiced on the patient above referred to, proved of no avail, as the unfortunate doctor died soon after; this time, for good. A. B.

DOMESTIC CORRESPONDENCE

NEW YORK LETTER FROM OUR REGULAR CORRESPONDENT.

NEW YORK, Jan. 3, 1885.

The annual collections in aid of the various hospitals were made, as usual, on the last Saturday and Sunday of the year, but it will not be possible, for some time yet, to announce the amount contributed. This work is under the charge of the Hospital Saturday and Sunday Association, an organization created for this special purpose, and each year its managers endeavor to render the machinery of its operations more and more perfect, so that the collections may be made as systematically and the contributions secured may be as large as possible. During the autumn and early part of the winter an active canvass has been carried on among the various trades through the agency of auxiliary organizations; and the number of these auxiliaries, through the labors of the central organization, has continued to increase until it now includes nearly all the leading lines of trade and industry in the city. Among the churches a systematic effort last year resulted in securing contributions from 220 congregations, as against 100 the year before.

Some have supposed that the offerings made on Hospital Saturday and Sunday would be used as an excuse for reducing or discontinuing subscriptions toward the support of hospitals at other times, and that the total revenue raised for the support of these charitable institutions would therefore be diminished rather than increased in consequence of the work of the Association. It is gratifying to note, however, that the opposite of this has been the case. In addition to the sums collected through the instrumentality of the Association—aggregating nearly $120,000 in amount during the past three years—there has been during the same period an improvement in the income of the hospitals from other sources, indicating that Hospital Sunday has been a stimulant, rather than a detriment, to the general flow of hospital charity. The reports of the Associated Hospitals show that during the past three years $201,650 has been expended on the enlargement of accommodations; that there has been an increase of $9,780 in the income from invested funds; that there has been an increase of $43,036 in the amount received from paying patients (at the same time that the number of free patients has increased from 6,698, in 1881, to 8,509 in 1883), and that the increase of income from contributions towards current expenses, other than those made in connection with the annual Saturday and Sunday collections, amounts to $22,774.

From the last annual statement of the Association, we learn that twenty hospitals now derive their support in part through this channel. The cost of maintaining these institutions last year was $546,380. To meet this outlay there is a regular income to be absolutely depended upon (of invested funds), of only $114,227, while the amount received from paying patients aggregates $131,241. The total number of patients treated last year was 11,409. Of this number 3,872 were free patients, and it was principally to maintain this feature of the work of the hospitals, and, if possible, to increase its scope and efficiency, that the annual collection was instituted. That it has in a considerable degree fulfilled its purpose is conclusively demonstrated by a comparison of statements of different years, such as is given above. It is thus pointed out that an important source of revenue, on which these institutions have in the past depended is likely to fail them this year, and perhaps for the future altogether, amounting in the aggregate to $35,000. At the last session of the legislature an act was passed, the practical operation of which will be, it is said, to appropriate to other uses (the police pension fund), all the moneys hitherto given to eleemosynary institutions of the city of New York, from the funds contributed to the treasury through the board of excise. The Association therefore made an earnest appeal for increased gifts, in order that the hospitals might not be compelled, on account of diminished resources, to restrict their growing work of charity. Last year the Saturday and Sunday collection amounted to nearly $45,000, and this year, to make up for the loss of the excise money and enable these institutions to carry forward their work, on even its present scale, $75,000 would be required. In order to stimulate the clergy in securing contributions from their parishes, it was announced this year that any minister who made a collection in his congregation, should have the right to call upon the general agent of the Association, to visit and secure the admission (if the case is a suitable one) to one of the hospitals of any sick person that he may recommend The Association also announced that it would take care of the sick poor among the trades contributing to the fund

In this connection it may be of interest to refer to some of the points of the observance of Hospital Day in London, as described in a recent letter to one of the New York newspapers In 1884 one of the many accessories was a grand féte at the International Health Exhibition, South Kensington, from the proceeds of which the Prince of Wales, as treasurer, turned over to the hospital fund the sum of £4,000 "Of course," the letter goes on to say, "what interests royalty interests the nobility, and this interest happily does not end with a subscription or the lending of a proud name What would New Yorkers say if, instead of seeing the collection boxes at the elevated railway stations fastened to a post, they should find them on tables in the most conspicuous places on the platforms, and each of them presided over by some fair leader of fashion? Yet this is one of the sights of Hospital Day in London, and was so the present year in spite of the fact that the day was as disagreeable as only a rainy day in London can be For the purpose of street collection the city is divided into 22 districts, each under the control of a special committee To these committees 1,400 tables, with boxes, were supplied, and as many ladies volunteered to take charge of them No other fact could speak more eloquently of the general public interest than this" In addition to the 1,400 stands in charge of ladies, smaller collection boxes were furnished to large numbers of young girls, with silk badges and pictorial handbills, who went everywhere about the city soliciting contributions, while to the Sunday collection no less than 1,500 churches and 120 Sunday-schools contributed As to the movement among the masses, 20,000 industrial and mercantile establishments received collection sheets, and the workingmen who actually contributed their mite through the various auxiliaries numbered fully 300,000 The good work was furthermore helped along by monster daylight and torchlight processions, accompanied by men carrying boxes and inviting donations, and by a number of grand ballad concerts, for which the leading talent of London volunteered its services

In the report of the State Charities Aid Association, read at the annual meeting of the Association in December, a number of topics of interest are touched upon The sub committee on hospitals has prepared two plans, one for a village hospital, accompanied by an explanatory leaflet, the other for a model poor-house, and traced copies of these plans may be had on application at the office of the Association An effort has been made by another sub committee to establish cooled water fountains in crowded tenement house districts in the summer Reports from the Metropolitan Drinking Fountain Association in England, it is said, show that these fountains supply a great want in large cities, diminishing sickness among children and intemperance A special committee on the insane has prepared two pamphlets, one containing a summary of legislation in England and the condition of lunatics in Scotland, and the other on the training of nurses for the insane This committee has received the cooperation of the Bellevue Training School for Nurses, and is now occupied in maturing a plan by which a number of women educated there as ordinary nurses for the sick may secure in one of the asylums of the city, a special training in the care of the insane "It is hoped," says the report, "that out of this preliminary work may grow a training school for nurses for the insane, where graduates of all training schools may be received, and which shall be as far-reaching in its usefulness and as fruitful of good, as the Bellevue Training School has been"

By decision of the courts the health officers appointed under the general act for the preservation of the public health passed by the New York Legislature are State officers, and are therefore subject to the civil service rules The Civil Service Commission has consequently adopted regulations as to the examination of such officers which require that the standing and fitness of applicants for the position shall be passed upon by a State Board of Examiners, consisting of five physicians to be designated by the commission, who, subject to the supervision of the latter, shall prepare the examination papers After the completion of the examination, which is to be held under the supervision of the County Judge, the papers are to be transmitted by him to the commission at Albany

Of the distinguished professor of anatomy at the University Medical School, Dr William Darling, F R C S, who died on Christmas morning, it is said that no one could quote a line of standard English poetry to him without his being able to recite the entire passage in which it occurred from memory. In regard to his own poetical gifts it is related that while he was living in London, a twisted paper was one day found in a young girl's skull among his specimens, containing an unsigned poem written by him, which was of such unusual beauty that a reward of fifty pounds was offered for the name of its author His anatomical collection is one of the finest in this country, and Dr Spitzka, who attended him in his last illness, and was one of his former pupils, asserts that the finding of a rare anomaly would delight the old man more than the discovery of the lost books of Tacitus would a German antiquarian

NEW YORK, Jan 24, 1884

The annual meeting of the New York County Medical Association was held Jan 19, when Dr Charles A Leale was elected President, Dr Edward G Janeway Vice-President, and Dr P Byrnberg Porter Recording Secretary On vacating the chair the retiring President, Dr William Detmold, made some interesting remarks in which he spoke of the movement for the defense of the National Code, which resulted in the organization of the State and county associations, as one of the most significant and brilliant events in the medical history of this country. He also alluded to the remarkable success which had been achieved by the Society during the first year of its existence, and to the permanent value of the papers read before it and the discussions upon them, and said that in a professional career which had now lasted over half a century there was nothing which he looked back upon with so much pride as the fact that he had been selected as the first President of the New York County Medical Association.

At the annual meeting of the New York Academy of Medicine, which occurred Jan. 15, Dr. Abraham Jacobi was elected President, Dr. Charles Carroll Lee Vice-President, and Dr. Louis Elsberg Corresponding Secretary. The report of the Library Committee showed that the library of the Academy now contains about 35,000 bound volumes and 9,000 pamphlets. During the past year there have been added to it 1,278 bound volumes, 1,875 pamphlets, and 7,814 medical journals. Five hundred dollars was appropriated for subscriptions to journals for the year 1885.

The paper of the evening, by Dr. W. Gill Wylie, one of the gynæcologists to Bellevue Hospital, was on "Diseases of the Fallopian Tubes and their Relation to Uterine Displacements and the use of Pessaries." In it he expressed the opinion that when the frequency and the great importance of diseases of the tubes is generally understood, the fascinating teaching of the mechanical pathologist, that most of the ills of women are due to uterine displacements, will fade to small proportions, and the relatively few lines now to be found in our text-books on salpingitis will increase rapidly, while there will not be so many hundred pages on cellulitis, displacements, and pessaries. He believes that salpingitis is nearly always caused by the extension of disease from the endometrium to the lining membrane of the tubes. The first effect of disease reaching a tube is to cause it to become engorged with blood. As it is loosely attached to the upper border of the broad ligament, it sinks lower in the pelvis, covering or folding over the ovary, and as the beginning of salpingitis, after labor or abortion, is often associated with an enlarged uterus, this organ sinks lower, while as the patient during the acute stage, is, as a rule, on her back, the fundus inclines backward. As soon as the discharge or the disease reaches the peritonæum, through the open end of the tube, the peritonæum becomes inflamed and lymph is thrown out, gluing the different organs together. As the acute stage subsides, the lymph contracts, bands of adhesion draw and distort the organs, and the folded, twisted and adherent broad ligament holds the uterus in its backward displacement. Repeated attacks are liable to occur, increasing the contractions and adhesions, and it is the rolled up ligaments and the tubes which fix the uterus backward; while it is the imbedded ovary and diseased tube in the hardened tissues of the broad ligament, which makes it next to impossible to insert a pessary and hold the uterus up without causing pain and running the risk of bursting or tearing a tube distended with septic or irritating fluid. When diseased tubes are plainly made out, and the patient is bedridden, or suffers to such an extent that after being clearly informed as to the effect and danger of the operation, she consents, Dr. Wylie considers complete removal of both tubes and ovaries, if both sides are affected, to be justifiable. He has now operated in fourteen cases, with the result of twelve recoveries and two deaths.

It will probably take a smaller mortality than that of one in seven to convince the mass of the profession that this operation is, as a rule, justifiable in the class of cases described by Dr. Wylie, where chronic invalidism is the worst that usually befalls the patient. It is true that in a few exceptional cases the bursting of a distended tube may result in general peritonitis, but even after peritonitis has set in the patients may sometimes be saved, as he himself points out, by a bold surgical interference. As a rule, therefore, it would seem to be better to defer the performance of laparotomy until after the occurrence of this possible accident. As regards ovarian cyst, the case is very different. Here the ordinary tendency of the disease is towards a fatal termination, and hence the operation would be entirely justifiable, even were the mortality vastly greater than it is. That Dr. Wylie was inclined to resort too frequently to laparotomy, seemed to be the general opinion of the speakers who took part in the discussion of the paper, among whom were such distinguished gynæcologists as Dr. Noeggerath, Dr. A. J. C. Skeene, of Brooklyn, and Dr. P. F. Mundé, editor of the *American Journal of Obstetrics*. Dr. Mundé spoke particularly of the great difficulty of diagnosis that was usually met with; but Dr. Wylie remarked in closing the discussion that since he had adopted his present plan of preparatory treatment he had found very little trouble in this respect. This consisted principally in applications for the purpose of softening the tissues, of glycerine and alum two or three times a week for a period of six weeks to six months, with an examination under ether at the end of that time in a considerable number of instances.

On the 18th of January, at the annual meeting of the Hospital Saturday and Sunday Association, it was reported that the collections for the hospitals this season had, up to that time, amounted to $30,988.90, and that the total, when all the money was handed in, would be at least $36,000. Last winter there was collected $43,062.74. It was stated that notwithstanding the business depression, the various trade auxiliary associations had done better than ever before; but that the churches had not contributed as liberally as last year, probably for the reason that on Hospital Sunday the weather was stormy.

Mr. Henry Lamb, of Rochester, N. Y., has offered through the American Public Health Association, the sum of $2,800 to be awarded in first prizes of $500 and second prizes of $200 for papers on the following subjects:

(1) Healthy homes and foods for the working classes.

(2) The sanitary conditions and necessities of school houses and school life.

(3) Disinfection and individual prophylaxis against infectious disease

(4) The preventable causes of disease, injury, and death in American manufactories and workshops, and the best means and appliances for preventing and avoiding them

All essays in competition for these prizes must be in the hands of the secretary, Dr Irving A Watson, of Concord, N H, on or before October 15, 1885, and the awards will be announced at the next meeting of the Association, in the second week of December, at Washington

Dr Fordyce Barker, the family physician of Gen Grant, is reported to have recently given the following account of his condition "Gen Grant's health has improved very much during the past few weeks, and the swelling in his mouth, which a few weeks ago made it difficult for him to talk or eat, has subsided in a great measure Some eight or ten weeks ago he was suffering from a swelling, accompanied by great pain, in the back of the tongue, and I called in Dr J H Douglas for the purpose of applying local treatment The General's smoking, in which he had been accustomed to indulge all his life to excess, seemed to irritate the tongue, although he was not conscious of its affecting his general system We therefore advised him to cut down his smoking to the first half of three cigars a day, as we thought it probable that it was the nicotine which accumulated in the last half of the cigar that produced the irritation He followed this advice for perhaps a week, and then gave up smoking entirely, apparently without the least disturbance to his nervous system, loss of sleep, or other unpleasant effect whatever This was remarkable, as he had been smoking from twelve to fifteen cigars a day The improvement in his condition since then is marvelous Under treatment by muriate of cocaine not only has the pain been greatly diminished, but the capillary congestion of the tissues has in a large measure disappeared " Dr Douglas intimated that the trouble in the tongue was of an epitheliomatous character P B P

MALIGNANT PUSTULES.

Sedalia, Mo, Jan 20, 1885

Dear Journal —In your issue of 17th inst, I notice a communication from Dr Leech, Jefferson Medical College, relating to ulcers of fingers While I do not approve of charging everything of this nature to syphilitic virus, it would certainly appear that in the cases cited there must have been some specific poison, as the ophthalmitis of the infant would clearly show The character of the ulceration, also, in my mind, would suggest animal poison Our literature upon the subject of localized pustulations is fearfully meagre, so far as causation is concerned Having just had a patient suffering in like manner, I was fearful of grave results No cause could be attributed for the local trouble I was treating the patient for a neurosis The general health was good The disease first manifested itself as a small blood-blister, about as large as a split pea, on the metacarpal phalange of the middle finger, right hand The suppuration extended to the bone The swelling involved the whole hand, and the general health was in consequence very much impaired I have met with several instances of this kind within the last few years, and have suffered some three attacks myself, all on the right hand These ulcers, to my mind, take on the form of braxy or malignant pustule, more than anything else I will say, for the benefit of the doctor, that I now take the precaution to cauterize all abrasions about the hand before making digital examinations or having anything to do with surgical cases, and especially suppurating surfaces Yours truly, Jno W Trader

RHINOLITH.

Louisville, Ky

My attention was called to the above subject by an article in a late medical journal It recalled to my mind a case I had three years ago, in the person of a young gentleman 21 years of age, who had been suffering from nasal catarrh since quite young Had been under the treatment, in the meantime, of many physicians for this affection The young man was scrofulous in appearance On making a careful examination of his nose, discovered well up in one nares a foreign body It was easily reached by a pair of forceps and removed without difficulty, with some pain, followed by slight bleeding The foreign body was about half an inch in diameter and flat, rather dish-shaped, or the shape of a large pearl button The surface was rough like a mulberry On sawing through the body it proved to be a rhinolith with an old-fashioned iron button, such as are used on the seats and backs of chairs and sofas, as a nucleus The cross section presented very much the appearance of a renal calculus Any history as to the length of time it had been there could not be gotten He suffered no more from nasal catarrh after the removal of the rhinolith W H Cheatham

BOOK REVIEWS

Transactions of the Medical Society of the State of New York, for the Year 1884 Cloth, 521 pages with appendix

A large part of the time of the Society was occupied in the discussion of the Code of Ethics The following are quotations from the anniversary address, "The Reciprocal Attitude of the Medical Profession and the Community," by Alexander Hutchins, A M, M D "There is a medical science, but if medicine were a science only, there would be fewer medical schools than now exist " "The genius of true scholarship the wide world over, is the search for truth and its free gift to mankind " "Whether the time is ripe to hang a man on microscopic evidence, or whether the time will ever come when the special vibrio of the assassin shall be diagnosticated from the spine of the burglar and the zoon of the concupiscent, are not questions angrily struggling for a reply " "The gifts of the degree are lavish The restrictive barriers are so loosely set up, and the final tests of fitness so daintily applied, that the former are cast down as easily as the latter is overcome " "The end of all medical learning is to make sick people well, to assuage the discomforts of the incurable and to promote the euthanasia " "No man has an inalienable right to practice medicine He can choose to do so, but the public may adjust the tests of his fitness " These quotations illustrate a few of the points considered in this eloquent and interesting address

The body of the report is made up of twenty-five papers, any one of which is worthy of critical attention, but time or space will not permit a full review, and so we will print a few of the most striking if not the most important points

Dr Arpad G Genter recommends Newber's methods of Canalization Shallow canalization for draining cavities beneath large skin-flaps consists in punching elliptical holes about $^1/_4$ in x $^2/_5$ in through the most dependent part of the flap Deep canalization as in wounds of the neck or axilla, consists in turning the skin-flaps into the bottom of the wound and securing them there by sutures The success of both methods in obtaining immediate union are reported as good

Dr Edward H Parker, as a result of observation and experience, estimates the cost of hospitals in small cities at $200 per bed

Dr A Jacobi recommends arsenic and digitalis in phthisis The former in doses of $^1/_{15}$ to $^1/_6$ gr per day, apparently as an alterative, and the latter in sufficient amount to act as a cardiac stimulant He has found arsenic particularly useful in the first stages of the disease Dr Drake in discussing the paper says that he has found it most useful in the latter stages The reader is at liberty to draw his own conclusion, to us it would appear that the drug in the dose given, chiefly acted on the digestive apparatus and was thus applicable to this or any other disease in which general mal-nutrition is an important factor

A New Method of Partial Extirpation of the Cancerous Uterus, by Dr Ely Van De Warker This consists of combined excision and cauterization with chloride of zinc

Dr John O Roe makes extensive reports of cases of hay fever radically cured by the removal or destruction *in situ* of irritable portions of the nasal mucous membrane

Dr Geo B Fowler called the attention of the society to the dangers of poisoning by potassium chlorate

Dr David Little, in speaking on the prophylaxis of summer complaint of infants recommends that overfeeding be avoided In illustration of the success of method he states "For twenty-one years I have been physician to the Rochester Orphan Asylum Each of these years had witnessed deaths from enteric disease until 1882 In the early summer of that year I said to the matron, 'Feed your babies but once in three hours during the day, but give them water to drink as often as they will take it' The matron carried out the instructions to the letter as she understood them, and fed them three times a day The following summer the original plan was carried out, the children being given a meal at night if water would not quiet them There were but two deaths, and these were children who were accidentally kept at the bottle all night

The Committee on Hygiene reported on the following subjects Mortality Tables and Epidemic Influences, Dr Janeway, Hygiene of the Ear, Dr Pomeroy, Sewer Gases, Dr Smith, High Houses, Dr Vanderpoel

Among others we note the deaths of George Burr, M D, and John Foster Jenkins, A M, M D C E W

A HANDBOOK OF THE DISEASES OF THE EYE AND THEIR TREATMENT By HENRY R SWANZY, A M, M B, F R C S G Cloth, 437 pages Illustrated New York D Appleton & Co

This book is designed by the author as a handbook for the use of students of ophthalmology It is condensed in style and broad in scope, covering all departments of the subject Its chief use to the practitioner will be as a book of ready reference when memory fails him in some matter of diagnosis or treatment The chapter on the eyelids treats of the various plastic operations for the relief of the distortions of these organs In chapter xiv the motions of the pupil in health and disease are considered Myosis may be caused by a diseased process irritating the pupil-contracting centre or fibres, or by one causing paralysis of the pupil-dilating centre or fibres, or by a combination of both The reverse of this irritation or paralysis, or both, would give rise to mydriasis

The following is a brief abstract from the portion of this chapter which refers to the value of the pupil in diagnosis

Irritation myosis is found in *a* The early stages of inflammatory affections of the brain and its meninges *b* In cerebral apoplexy, thus differentiating from embolism *c* Inter-cranial tumors at the origin of the third nerve or in its course *d* At beginning of attack of hysteria or epilepsy *e* In tobacco amblyopia *f* As result of long maintained effort of accommodation, as in certain trades *g* As a reflex action in ciliary neurosis

Paralytic myosis occurs in spinal lesions above the dorsal vertebræ, as in injuries and chronic forms of inflammation

Irritation mydriasis occurs *a* In hyperæmia of the cervical portion of the spinal cord, and in spinal meningitis *b* In new growths in the cervical portion of the cord *c* In cases of tumors and other causes of high intercranial pressure *d* In spinal irritation of chlorosis or anæmia *e* In intestinal irritation from worms or other causes *f* In psychical excitement, may be unilateral

Paralytic mydriasis may be due either to a paralysis of the pupil-contracting centre, or as the result of the stimulus not being conducted from the retinæ to that centre The former may be found *a* Sometimes in progressive paralysis where at first there was myosis *b* In various diseased processes at the base of the brain affecting the third nerve *c* In a later stage of thrombosis of the cavernous sinus *d* In orbital pressure on the ciliary nerves *e* In glaucoma *f* In cases of intraocular tumors In cases where the cause is simple failure in the transmission of the stimulus from the retina, contraction of the pupil will take place on convergence of the visual line

In illustration of the test for color blindness there is appended to the book a sample card of the various worsteds used in the test C E W

Lectures on Some Important Points Connected with the Surgery of the Urinary Organs By Sir Henry Thompson, F R C S, M B, Lond Philadelphia P Blakiston & Son Pp 147

This work is issued in the cheap students' form (cloth or paper) and is uniform with former volumes by the same writer Included in this volume we find (Chap III) the essay on "Tumors of the Bladder," and digital exploration of that organ This includes all that was found in the little book, "Tumors of the Bladder," with the exception of the colored plates, which were of slight importance

The remainder of the chapters are supplementary to what he has repeatedly published In the discussion of improved lithotrity full credit is given to American surgeons for modern improvements, but exception is taken to Bigelow's introduction of the word "litholopaxy" as unnecessary The author asserts that the increased size of Bigelow's instruments is objectionable, while admitting that "Bigelow's achievement has been to demonstrate that crushing a stone, even if large, and removing all the fragments from the bladder at one sitting, is a safer proceeding than dividing the work between two, three or more sittings," p 119

In objecting to large lithotrites and evacuators, Sir Henry really shows that he has not yet thoroughly grasped the vital point in the American method, namely, the use of vastly larger and more powerful tubes and crushing instruments

Bigelow's lithotrite compares with Thompson's in point of efficiency for *any* stone about as the rifled gun compares with the smooth-bore

This instrument, however, fails to appear among the cuts given of "improved" lithotrites, p 123–124, and even the one designated, "Fenestrated Lithotrite, very powerful" (Fig 22), is far inferior to the new American instrument, for it lacks the long beak which is so useful in holding the membranes away from the jaws This is ignorance or something worse—bigotry

A man claiming the position of world-known specialist and authority, is bound to give more faithful information than this when he attempts to impart instruction Clearly his business was to have known the fact that Bigelow's apparatus has completely superseded his own, and if he has not already purchased and tested the instruments he should do so at once

On page 120 we find

"We must recognize the importance of not inflicting any needless injury on the urethra and bladder, and should therefore always select the smallest lithotrites and evacuators which possess the strength and capability adequate to crush and remove the individual calculus to be dealt with "

Now, experience enough has been had on this side of the water to prove beyond cavil that the largest instruments are the ones which cause least injury even on very small or soft calculi, because, having once seized the stone, they annihilate it, often, with a single movement of the broad jaws, and thus with far less manipulation than in the smaller lithotrites As to distending the urethra, *quid interest?* The urethra is not diseased It is the inflamed and irritable bladder we wish to spare all possible contusion, and this we accomplish by using the largest possible instruments which the urethra will admit Moreover, clinical experience has shown the use of Bigelow's large tubes and instruments to be harmless, all of which Sir Henry Thompson could have known, had he chosen to avail himself of the abundant facts now before the public E W A.

Transactions of the New Hampshire Medical Society at its Ninety-fourth Annual Session, 1884 Paper, 213 pages

From among the various interesting papers we abstract the following, from "Respiratory Irrigation in the Treatment of Empyema," by E S Berry, M D The author considers that the steps in the treatment of empyema are these Aspiration, free drainage and frequent washing out of cavity, Listerism, suction to the compressed lung The plan of treatment was suggested by C McIvor Goyder, Esq, in the *Lancet* of March, 1881 The patient was a previously healthy boy, ten years of age After three months' sickness, with fever and pain in side, etc, an opening was made in the sixth interspace on a line with the axilla A tube was passed into the opening This, after leaving the chest, passed through a rubber disc, about five inches in diameter, which fitted close to the chest-wall and held the tube in place Over this a rubber bandage encircled the chest This tube passed through the clothing and under a solution of salicylic acid, which was placed in the patient's pocket Whenever the bottle was changed a stop cock in the tube was closed It will be seen, by a study of the physics of this apparatus, that while it is convenient and clean, it fully meets the indications for treatment above enumerated The respiratory movements effect a circulation between the cavity of the chest and the bottle, while the vertical height of the fluid column in the tube determines the amount of suction on the lung On raising the bottle the fluid will flow into the chest, and thus the cavity can be washed In the case reported recovery was rapid

C E W

The Laws of Health Physiology, Hygiene, Stimulants, Narcotics By Joseph C Hutchinson, M D, LL D Cloth, 223 pages Illustrated

This elementary work greatly resembles the other text-book by the same author which was noticed recently in this journal

HISTORY OF THE DISCOVERY OF THE CIRCULATION OF THE BLOOD By HENRY C CHAPMAN, M D Philadelphia P Blakiston, Son & Co Cloth, 56 pages, price $1

The development of an idea is like the growth of the organism that produces it It is neither spontaneous, instantaneous, nor in a continuous line of evolution The first inception is in the observation of a fact Through other observations and the elaboration of new thought it assumes its embryonic forms, at last the labor of some greater intellect delivers it from its enshrouding mysteries, and it becomes a self-sustaining, active power In the work before us the author shows this to have been the case respecting the idea of the circulation of the blood

He reviews the various fragmentary and incomplete notions of the ancient writers, and after showing that the work of Harvey was only incomplete in his ignorance of the capillary circulation, thus recapitulates the principal epochs

"1 The structure and function of the valves of the heart Erasistratus, B C 304

"2 The arteries carry blood during life, not air Galen, A D 165

"3 The pulmonary circulation Servetus, 1553

"4 The systemic circulation Cæsalpinus, 1593

"5 The pulmonic and systemic circulation Harvey, 1628

"6 The capillaries Malpighi, 1661 "

NEW REMEDIES

BY J CHRIS LANGE, M D , PITTSBURGH, PA

Read before the Mott Medical Club, of Pittsburg, Jan 28 1885

MR PRESIDENT AND GENTLEMEN —In order that the scope of this paper may be understood at the outset, it is necessary to state to what preparations and productions the name, New Remedies, is therein applied , and, also, that the paper is limited to a desultory consideration of the popularity, in the profession, of new remedies, of the foundation of this popularity, and of some conclusions that may be adduced from it

The class of therapeutical agents to be herein considered in the limited aspect which has been indicated, embraces, under the generic name of New Remedies, all preparations and productions not officinal in the United States nor foreign pharmacopœias, with the single exception of that very limited number of such agents which have been proven, beyond reasonable doubt, to possess the qualities attributed to them , this proof being founded upon evidence furnished by an extended clinical experience, at various hands, irrespective of and uninfluenced by the results of theoretical speculations, of chemical or microscopical researches, and of experiments on animals

That the therapeutical agents entitled New Remedies, are popular in the profession, and that their popularity is on the increase, cannot be truthfully denied An inspection of the cases and shelves of any apothecary will show an accumulation of them which is a demonstration of their demand by the profession The flourishing condition of the numerous establishments devoted to their preparation and production, is, also, proof that they are popular The magnitude of these establishments, and the magnitude of their correspondence and transactions, as compared to those which limit themselves to the preparation and production of officinal remedies, is evidence determining the same conclusion If further argument be needed to establish the existence of this popularity in the profession, it may be cited, as additional evidence in proof, that this popularity is very well appreciated and employed, inasmuch as two medical journals are published and circulated in this country, under the popular title of New Remedies, one of which, perhaps both of which, enjoy a large and ready sale

When it is asked upon what this popularity is founded, in other words, upon what grounds the extensive employment of new remedies, by the profession rests, no sophistry can obscure the answer, if the question be lucidly considered The answer is arrived at as inevitably as reluctantly , the answer is not a flattering one to the profession An endeavor to discover good and sufficient reason for the existent employment of these remedies, is a natural and laudable one , but it is a fruitless one, also It is proper to inquire, then, What is a good and sufficient reason for the exhibition of any therapeutical agent in any case of disease? The answer to this is, A clear indication, founded upon the results of clinical experience This is the unalterable law All time can only disseminate its wisdom , it can never overthrow it Every result of the most elaborate studies and experiments, which shall be made by ways and means and appliances of which we have, as yet, no conception, all that all time may do, must be submitted to that infallible standard of judgment, clinical experience, and must be proven there, before it is accepted This is the law, and must be always Let this law be applied to the employment of the remedies under discussion, in the treatment of disease Is this law observed in the treatment of disease by the exhibition of new remedies? The answer must be, No , it is not They are not employed, then, in consonance with the indications furnished by clinical experience? They are not employed, because of the only good and sufficient reason, that their effects are known and desired? And again the answer must be, No , they are not

It is obvious that opponents of this conclusion are many and great They are active and energetic also, their cry, Progress—Original Observation, is heard and applauded throughout the land But it is affrighting and dismaying to the true lover of his profession He appreciates the power of zeal He recognizes the contagion of enthusiasm He has witnessed the large following of more than one brilliant illusion He is aware that brilliancy, enthusiasm, and zeal are more often effective of evil to science, than of good to it, that these qualities more often serve to retard, than to further its progress, and that their results, when weighed in the balance of truth, are thrown in air,—a nothing, by the accumulated evidence of centuries

MR PRESIDENT AND GENTLEMEN —In order that the scope of this paper may be understood at the outset, it is necessary to state to what preparations and productions the name, New Remedies, is therein applied, and, also, that the paper is limited to a desultory consideration of the popularity, in the profession, of new remedies, of the foundation of this popularity, and of some conclusions that may be adduced from it

The class of therapeutical agents to be herein considered in the limited aspect which has been indicated, embraces, under the generic name of New Remedies, all preparations and productions not officinal in the United States nor foreign pharmacopœias, with the single exception of that very limited number of such agents which have been proven, beyond reasonable doubt, to possess the qualities attributed to them, this proof being founded upon evidence furnished by an extended clinical experience, at various hands, irrespective of and uninfluenced by the results of theoretical speculations, of chemical or microscopical researches, and of experiments on animals

That the therapeutical agents entitled New Remedies, are popular in the profession, and that their popularity is on the increase, cannot be truthfully denied An inspection of the cases and shelves of any apothecary will show an accumulation of them which is a demonstration of their demand by the profession The flourishing condition of the numerous establishments devoted to their preparation and production, is, also, proof that they are popular The magnitude of these establishments, and the magnitude of their correspondence and transactions, as compared to those which limit themselves to the preparation and production of officinal remedies, is evidence determining the same conclusion If further argument be needed to establish the existence of this popularity in the profession, it may be cited, as additional evidence in proof, that this popularity is very well appreciated and employed, inasmuch as two medical journals are published and circulated in this country, under the popular title of New Remedies, one of which, perhaps both of which, enjoy a large and ready sale

When it is asked upon what this popularity is founded, in other words, upon what grounds the extensive employment of new remedies, by the profession rests, no sophistry can obscure the answer, if the question be lucidly considered The answer is arrived at as inevitably as reluctantly, the answer is not a flattering one to the profession An endeavor to discover good and sufficient reason for the existent employment of these remedies, is a natural and laudable one, but it is a fruitless one, also It is proper to inquire, then, What is a good and sufficient reason for the exhibition of any therapeutical agent in any case of disease? The answer to this is, A clear indication, founded upon *the results of clinical* experience This is the unalterable law All time can only disseminate its wisdom, it can never overthrow it Every result of the most elaborate *studies and* experiments, which shall be made by ways and means and appliances of which we have, as yet, no conception, all that all time may do, *must be* submitted to that infallible standard *of judgment*, clinical experience, and must be proven there, before it is accepted This is the law, and must be always *Let this law be applied to the employment of the remedies under discussion, in the treatment of* disease Is this law observed in the treatment of disease by the exhibition of new remedies? The answer must be, No, it is not They are not employed, then, in consonance with the indications furnished by clinical experience? They are not employed, because of the only good and sufficient reason, that their effects are known and desired? And again the answer must be, No, they are not

It is obvious that opponents of this conclusion are many and great They are active and energetic also, their cry, Progress—Original Observation, is heard and applauded throughout the land But it is affrighting and dismaying to the true lover of his profession He appreciates the power of zeal He recognizes the contagion of enthusiasm He has witnessed the large following of more than one brilliant illusion He is aware that brilliancy, enthusiasm, and zeal are more often effective of evil to science, than of good to it, that these qualities more often serve to retard, than to further its progress, and that their results, when weighed in the balance of truth, are thrown in air,—a nothing, by the accumulated evidence of centuries

As a pertinent illustration of this reference may be made to the *furor* created in this country and extended throughout the world, some ten years since, by the radicalism—the positivism—of deluded members of the profession with the cancer-plant, cundurango. And again, how this experience was repeated when the profession was informed, from England, of the curative properties, in cancer, of chian turpentine. With such apparently decisive evidence were these fallacies promulgated throughout the world, that they were received with credence, were largely adopted, and were allowed to displace well-tried, well-proven, and well established treatment. The pain, the misery, the hopes revived to be but crushed again, the loss of life,—all must be ascribed to the brilliancy, enthusiasm and zeal of the promulgators of the delusions referred to.

But the truth of the proposition herein submitted, that new remedies are extensively employed by the profession, irrespective of the results of clinical experience, or without the existence of any results of clinical experience regarding their employment, will be denied. The proposition will be assailed by those who employ these agents, because it implies that their employment rests upon insufficient grounds, or in other words, if the gravity and responsibility of the matter be considered as influencing life and health, that it is unjustifiable. It becomes necessary, therefore, to examine the grounds upon which the use of new remedies rests. An endeavor to ascertain these is met, first, by a mass of evidence from medical practitioners of all grades. In it the certificate of utility, excellence, or specific virtue, obtained from an obscure "swamp doctor," is printed side by side with that of the eminent practitioner of a metropolis, and that of the learned college professor. The unanimity of conviction of the excellence of such a remedy, expressed and advertised from many and such varied sources, is a cause of, and is seized upon in justification of, its employment. The office of the physician is, to day, flooded with such evidence. It embraces favorable and commending notices, from the before-mentioned sources, of remedies for every class of diseases, and for every disease—from a table water to a specific for syphilis. It is furnished in circulars, letters, treatises, and in the advertising columns of medical journals. Who so assiduously supplies this evidence? The flourishing manufacturers and producers of the remedies. What is the motive in the expensive manufacture and circulation of this evidence? It is to persuade the profession to employ the remedies, and thus to create a consumption, or sale, for them. The more evidence the producers can offer, and the more convincing they can make it, the greater will be the sale of their products. This evidence, under the name of clinical experience, convinces members of the profession of the utility, excellence, or specific virtues of these remedies. The motives of these manufacturers are venal only. Irrespective of any good or bad qualities their remedies may possess, the success of these producers in disposing of their wares, depends entirely upon their ability to create and disseminate such evidence. The evident prosperity of these producers is a reflection, in all aspects, upon the profession, their success is a detriment to it, it is also a demonstration of a credulity in the profession, deserving the qualification superstitious. The ways and means the producers employ to create the evidence upon which their prosperity is founded, it is not within the province of this paper to consider.

This evidence which, by its creators and promulgators, is made to appear to be the result of clinical experience, if considered with the deliberation a medical education should breed and the practice of medicine should foster, will appear at its intrinsic value. It is characterized by a bias, by an evident pre-determination to find, in the remedy commended, those qualities which are attributed to it, or those effects which it is desirable should follow its administration. This bias is pronounced by the absence of all consideration of the natural course of disease. This evidence is characterized by bold assertions which defy contradiction, or by speculative insinuations which seem to fear it, both of which are antagonistic to very well established laws of disease. This evidence lacks all circumspection, and all discrimination of such events natural to disease, from such others as may be properly ascribed to a remedy. This evidence ignores the laws of disease, or makes these laws appear inoperative in the presence of a remedy. Further, this evidence is characterized by a spirit of surprise at the magnitude of the beneficial results and effects of remedies, by a spirit of superlativism in the consideration of the superiority ascribed to remedies, and by a spirit of the importance of making known, as rapidly and as emphatically as is possible, such effects and results. This tumultuous spirit desires no confirmations of observation or inference, it does not admit the possibility of erroneous conclusions, and it debars all cavil and all doubt. A spirit totally at variance with that which pervades true scientific observation. Again, this evidence is characterized by a wonderful rapidity of growth: two years ago a certain new remedy was thrust upon the profession, which, simultaneously with its appearance, was commended by the evidence, characterized as above, and dated at points from New York to California, of fifty-eight practitioners, of whom one is a medical author, and of whom three occupy chairs in medical colleges. Not long before, a new remedy was introduced by the evidence, characterized as above, of its utility and excellence, this evidence was obtained from—among many others—thirteen representatives of medical colleges. Again, this evidence is characterized by a perversion of rationality. The following is an instance of this. A physician relates the cure of three women of "sterility." He relates, then, how these women, before their cure, *i. e.*, while they were "sterile," repeatedly aborted in early pregnancy, how they were cured of this habit by the specific administered for the purpose, and concludes by saying, "It may be objected that I used iodoform and iron in these cases, but this was only done on account of their anæmic condition, and to restore lost vigor." Another reports, "Mrs. P., abscess of left lung, usual symptoms." Gave the new specific. "After two days she raised about a pint of greenish-yellow pus Continued medicine six days, lung troubles all removed "

These characteristics are prominent and abundant throughout this evidence Can it then, by the greatest strain upon leniency and courtesy, be dignified by the title, clinical experience? The answer, compelled by its consideration is, Most certainly not It demonstrates the lack of that conservatism which is essential to endow clinical observation with value It demonstrates the lack of many other qualities and requirements, also essential to clinical observation, which it is not within the province of this paper to designate and comment upon

Other ground for the existent extensive employment of new remedies is formed by what has been called, elegant pharmacy It is, beyond a doubt, of prominent importance to the welfare of medical science, that palatable and well-looking preparations be dispensed to the public A considerable portion of the public has been alienated from regular medicine by the nauseating and ill-looking preparations sometimes administered to it, this is likely to happen when ailments are considered to be of little gravity, on which occasions irregular and illegitimate systems of practice are, for the avoidance of unpleasant doses, preferred and patronized To have palatable, well looking, neatly labeled and packed preparations dispensed, is a desideratum deserving of great estimation Although a matter of much importance, it was neglected by the pharmacists throughout the country The value of this art was appreciated, however, by the manufacturing chemists, cultivated by them, this field has borne good fruit As illustrative of this, the elixir, which, to a great extent, has displaced the tincture, is an example So popular has it become, and so deserving is it, that it has been admitted to the United States pharmacopœa Another example of the progress of this art, is the coating of pills, which is a perfection of utility and elegance In so far as these and similar desirable changes go, the profession is indebted to the manufacturing chemists But their endeavors have been productive also of much evil And this evil it is which forms another ground upon which the results of clinical experience are ignored in the employment of new remedies

This evil presents itself in the endeavor, by manufacturing chemists, to force upon the profession the use of certain elegant new remedies, which consist of combinations of well known agents, with published formulæ, in agreeable vehicles and fine dresses, and under delusive and ridiculous names The forcing process employed is the abundant circulation of medical evidence testifying to their utility, excellence, and specific virtues, which evidence is accepted by those in the profession who use these remedies, as clinical experience These "happy combinations" are condemned by scientific medicine because they originate in the chemist's laboratory and not from the clinician's observations To attach particular value to them, is to believe that the physician is incompetent, or is less competent than the chemist, to combine and prescribe remedies for disease,—a palpable absurdity They are condemned by scientific medicine, also, because its practice requires—among other things—an adaptation of therapeutical agents to individual cases of disease, and because its spirit wisely denies that a certain remedy, or a certain combination of remedies, is always indicated in a certain disease

The profession is justly indebted to a chemist who will make a remedy agreeable to sight, taste and smell,—an ability a chemist may possess and a physician may lack, but when the profession allows itself to be persuaded by a chemist that his combination of remedies, by reason of its special therapeutical properties, is preferable to a combination the experience of the profession might dictate, then the profession deserts scientific medicine Its practice rests upon no such unstable foundation Its intelligence instinctively abhors gratuitous speculations, and rejects all conclusions not supported upon clinical evidence Its discipline is enforced by knowledge which debars experiment Its foundation is the principles its practice has established The employment of the remedies created in the laboratory, and in the study, is antagonistic to the spirit of scientific medicine The evidence as to utility, excellence, and specific virtues, characterized as above stated, and coming from those who employ these remedies, is worthless to scientific medicine, and is not entitled to rank as the result of clinical experience It is promulgated with a venal—a commercial motive, only Contrast the manner of the spread of this evidence with the manner of the spread of that of an agent deserving consideration, for example, muriate of cocaine—new, also, for its present use How is such evidence spread world wide? This requires no capital, no advertisement, no reams of certificates, no polite emissaries to stock a doctor's office with samples Such evidence is promulgated alone by that glorious and beneficent characteristic of our profession, humanity!

But this extensive employment of new remedies by the profession has other causes, causes which underlie and determine the activity of those which have been considered There exists in a moiety of the profession a controlling desire to accomplish impossibilities This desire is generated, most certainly, by laudable and commendable instincts and motives but it is nevertheless unreasonable, and, unless held in subjection by scientific knowledge, will lead to much evil It is the desire which prompts attempts to accomplish what, in the great majority of diseases, is impossible the abortion of disease, or the limitation, as regards time, of the course of disease The possession of this desire, unguarded by a familiarity with, and regulation by the natural course of disease, is a most unfortunate one The attempts to control disease by potential agents, irrespective of its natural course, constantly afflict the possessor of this desire with the disappointments and vexations of failure His not less earnest because mistaken course, is thus beset with unpleasant experiences, which are substituted for the satisfaction and pleasure which should cheer the physician as he daily observes the expected and interesting course of diseases and their intrinsic tendency to recovery A physician who, in the hope of achieving abortive effects upon disease by the exhibition of potential agents, habitually interferes with the normal course of disease, will not grow and gather the reliable and valuable experience which he would accumulate were he to content himself with observing, and when necessary directing, the course of disease The constant failure of his therapeusis will result in his underestimate of potential agents The confusion of his clinical experience will obscure his perception of the arrival of events in disease, which imperatively demand decisive treatment This desire breeds, also, a perversion of intellect, which diverts even the possession of skill and positive knowledge from its proper use The practitioner who overestimates the importance of new remedies, is very apt to underestimate that of well established ones This aberration is visible in the eager expectancy with which he studies and employs new remedies, in the exultation with which he notes beneficial changes, in the certainty with which he ascribes these changes to his remedy, and in his discovery of the evanescent fallacies, which leave him helpless in painful uncertainty, eager to seize and ready to rely upon the next deception which chance may bring to his notice As illustrative of this, the following occurrence is pertinent A medical practitioner of this city, seized by an acute inflammatory affection, presented an abnormally high temperature His physician, with the additional stimulus of friendship and fraternity in medicine, devotedly exerted himself to render the best possible service Heedless of the existence of well established agents to effect the desirable reduction of temperature, he employed for this purpose a new remedy highly commended for its antithermic qualities, an alkaloid built up synthetically in the laboratory of the chemist With the best intentions he persisted in its use, without any effect, until his patient's condition became extremely alarming and additional advice was solicited, which, by means of the previously despised, well-established antipyretics, rescued his patient from impending death

The possession of this desire and the uncertain state of mind, as regards remedial agents, produced by exercise of this desire, in conjunction with the unfortunate results of treatment which must follow, will compel—it might almost be said—a practitioner constantly to employ new remedies, when the printed evidence of their utility, excellence, and specific virtue constantly surrounds him Exemplifications of this picture are numerous, and from them may be learned how the cry, Progress, unknown to its utterers, but in reality, may mean retrogression

Nothing contained in this paper is intended to support or excuse fogyism, or to depreciate the value of the results of original observations of new remedies if these be attained in proper and reliable,—*i e*, scientific—manner, and by those possessing the necessary acquirements and opportunities to make and record them So qualified, the observation of the effects of new remedies will result in a class of evidence, very different from that now at our service The limits of this paper forbid a consideration of the requirements of such scientific observation, as well as that of a subject of equal, if not of greater, importance and interest, namely, the continued study of the natural history of diseases, together with the modifications of the natural course of diseases, which may be effected by the exhibition of well established therapeutical agents This latter subject is, to the practitioner, of vastly more importance than the former, and will repay him richly for all the time and pains he may devote to it

It has been emphasized above, that the only good and sufficient ground for the administration of a remedy in disease, is a clear indication for its use It is appreciated, at the same time, that to confine the administration of medicines in disease within the letter of this law, is impracticable The understanding of medical practice existent in the public mind determines this impracticability The era of the placebo has not yet expired But the reign of the placebo comes entirely within the spirit of the law The placebo is clearly indicated in the course of disease, by the absence of all indications for potential agents, in conjunction with a result of the existent medical education of the public The employment of the placebo when thus clearly indicated, is followed by the most salutary results

1222 Penn Avenue

ALCOHOL IN THE SICK ROOM

BY T D CROTHERS, M D ,

Superintendent Walnut Lodge, Hartford, Conn

Clinical studies of the histories and early causes of many cases of inebriety, indicate that the injudicious use of alcohol or its compounds, prescribed as medicine, have been the starting point of many lamentable cases There can be no doubt that such cases are more frequent than we are aware of, also that irregular practitioners and domestic prescriptions are responsible for a large share of them

A book on domestic medicine, quite popular a few years ago, and somewhat widely circulated, written by an irregular, in which alcohol was the common remedy recommended, has been the exciting cause in several well-authenticated cases of inebriety, and has probably been the origin of many others The free use of bitters, containing alcohol in combination with very impure drugs, is responsible for a large per cent of such cases Remedies that appear recommended in the newspapers, with alcohol as a base, are also dangerous Medical men who have become enthusiastic as to the possibilities of alcohol, have not infrequently prescribed it for every condition of exhaustion for a long time The results in many cases have been a possible transient good, at the expense of propagating another disease more intractable and disastrous than the one they sought to relieve The frequency of inebriety arising from such causes has brought out a special medical declaration in England, signed by most of the leading physicians and surgeons of the kingdom, calling attention to the belief that the inconsiderate prescription of large quantities of alcoholic liquids by medical men for their patients, gave rise to intemperate habits, asserting that alcohol, in whatever form, should be prescribed with as much care as any powerful drug, and that the directions for its use should be so framed as not to be interpreted as a sanction for excess, or necessarily for the continuation of its use when the occasion is past Bad results are not always clearly traceable, and do not follow in every case, or even in a progressive order, and hence are doubted As an illustration, an excellent physician said he could not, in his long experience of the use of alcohol as a medicine, recognize a single case of inebriety which followed from alcoholic prescriptions that he had given A few weeks after a case of inebriety was brought to me for consultation, in which the patient had taken by this physician's order brandy and cod liver oil for eight months, for incipient pulmonary hæmorrhage He recovered in part, but became an inebriate The brandy with cod liver oil was the first alcohol ever taken The disease of inebriety may be compared to malaria, which, having once pervaded the system, leaves a peculiar predisposition, which only awaits a train of exciting causes to spring into activity

Inherited conditions of the organism may exist which give direction to weakened functional activities, exploding in inebriety with great certainty The medical prescription of alcohol to such persons becomes the exciting cause, awakening and fixing conditions which may not break out at once, but sooner or later will be manifest It is a fact well established in medicine that certain illy defined states of the organism decidedly contraindicate the use of particular remedies This is manifestly so in the use of alcohol in many cases, particularly when there exist in the history indications of neurosal degenerations, or decided inebriate tendencies, or conditions of functional disorder, which are susceptible to and likely to take on organic disease Anæmia, neurasthenia and neuralgia, and some conditions of rheumatism, also asthenic diseases, belong to this class, and are often developed into serious disease by alcohol When alcohol is given medicinally any length of time, the danger *is greatly enhanced* The following are presented as typical cases, occurring in the practice of excellent physicians

Rev —— was the only son of a New York merchant, who became an inebriate at forty-five, and died His mother was an ambitious woman, always struggling into circles above her, and very nervous and impulsive When a young girl, she had St Vitus' dance, and at the birth of her son had convulsions She recovered with an entailment of neuralgia, and various functional disorders Her father was a hypochondriac for many years, and her brother, the uncle of the Rev ——, drank more or less all his life It is evident from this that a marked neurosal diathesis existed, with a tendency to inebriety, depending on circumstances Rev ——, at twelve, developed a very sensitive nervous system, and at puberty suffered for six months from low nervous fever and general anæmia He was noted in his academical studies for his great mental capacity and irregular habits of work In college he secured several prizes, and was one of those good-natured boys who waste much time during the day and make it up at night He drank soda and beer, and lived well During his studies at the seminary, preparatory for the ministry, dyspepsia came on, for which he used bitters, with some relief At graduation he was in appearance slim, of light hair, with a strongly marked nervous diathesis His first charge, a Baptist church, brought him in contact with a people who gave rich dinners, and lived high His dyspepsia returned, and bitters were used with apparent good results Two years later he married, and was called to a city church, when the mental strain was continuous and severe His habits of living were more or less irregular, and his dyspepsia came and went, although he continued to take medicine for this and various functional disorders His pulpit work was impulsive and exhaustive For weeks he would manifest great power and energy, then relapse into a condition of debility and indifference After a revival season of much excitement he went away to the seashore to rest, and drank a bottle of porter a day, with great relish and apparent benefit He returned to his work and continued drinking porter His nervousness increased, and a low nervous fever followed, ending in general exhaustion and functional paralysis, from which he recovered very slowly The next two years were spent in retirement, and then he became a pastor in a village church, and preached once a week Five years later he had grown more nervous and neuralgic, any special excitement caused great prostration He was often unable to continue his sermon, from want of control of his nervous system His mind seemed clear He would work out in the garden for days, or go hunting or fishing, then remain in the house for an equal or greater length of time He was firmly opposed to the use of alcohol in any form, but continued to use different kinds of drugs, and sometimes bitters, with electricity, etc Exhaustion, both mental and physical, with persistent neuralgia, became more and more prominent symptoms His church sent him to Europe for three months While travelling on the continent he drank wine freely, and came home much better A year later his old prostration and nervousness came back with renewed energy His family physician called a consultation, and after a long examination of the case recommended Bourbon whisky, with cinchona bark and other tonics The relief was marked and the effects very agreeable Increasing doses were demanded and soon he was intoxicated Then he became passionately fond of whisky, using it in large quantities four or five times a day A few months later he drank to intoxication, and from this time the progress of the case was rapid He resigned his church to avoid the publicity of drinking Retiring to the country he is to day an inebriate, broken down and drinking to intoxication at every opportunity His mind is enfeebled and full of delusions of self-control and ability to stop at any time

This patient inherited a tendency to nerve degeneration, his early habits indicated an alcoholic diathesis or condition of exhaustion which sought relief through the appetite Mental labor and strain of all kinds reacted in this way As he grew older this exhaustion became a sense of general agony and depression, and the organs seemed in sympathy with an undefined want, which alcohol of all other substances alone seemed to relieve His visit to Europe, with a free indulgence of wine, fixed this tendency which had grown gradually from year to year, through the use of wine and bitters and other remedies The untimely prescription by the physician precipitated his case and, as it were, exploded a long train of diseased tendencies

CASE 2 —John H , a farmer His parents both died of consumption in middle life His grandfather drank very hard after sixty years of age, and one of his uncles was considered insane Two sisters died of consumption, and one brother suffered many years from rheumatism, and finally died of some intercurrent affection Nothing unusual happened in childhood, except a severe attack of scarlatina, from which he suffered two or more years, with a discharge and deafness This passed away without entailment and through early youth up to manhood he was in good health and apparently of robust mind and body He worked on the farm from seventeen years of age, doing the usual work

At twenty-four he married and became owner and manager of a large farm He was temperate in everything except eating At twenty eight he was laid up in bed from a fractured femur, and suffered from a bed sore and low form of fever, for which he was given porter and brandy, and eggs, for many weeks On recovery he showed a marked taste for beer, and continued its use regularly This was continued for over a year, and alternated with whisky, during which time he became intoxicated several times From various causes he signed the pledge and reformed, though using cider occasionally At forty he began abruptly to use whisky, at a political meeting, and became intoxicated, he continued to use it for some weeks and then stopped, as before From this time he was nervous and very excitable and easily prostrated after any unusual event that interested him He became a hypochondriac and patronized quack and patent medicines for supposed heart disease At fifty he gave up his farm and came to the city to live He was nervous and full of whims and notions, and impulsive in his way and manner, using cider and occasionally beer The changed circumstances of city life, and want of healthy occupation increased his nervous prostration and mental disquietude Hypochondriac delusions came on and a physician was called, who treated him for six months, then came a council of physicians, who agreed that a whisky punch and a bottle of porter a day would answer the indications best A few weeks later he was intoxicated every night No effort to stop was of any avail now His mind sank down to the level of an animal whose only ambition was its gratification, particularly in drink He seemed maniacal if alcohol was withheld from him The physician who prescribed for him, pronounced it incipient dementia, and urged that he be under restraint A few months later he died in a state of coma from alcohol This case was also marked from the strong inherited tendency to drink, which was present in the consumptive and rheumatic diatheses of the family These diseases are often associated with inebriety, and noted as phases of this disorder Inebriety not unfrequently appears in the next generation, in rheumatic or consumptive diathesis The first intimation of this diseased tendency was intemperate eating After the fracture of his leg and its attendant debility, a desire for beer and stronger alcohols was prominent, developing and fixing all previous latent tendencies This he was able to control until a few years later it burst out again with abruptness, and from this time out there was evidence of permanent alteration of disposition and intellect. The emotions and motor functions seemed changed. And when he came under the care of the last physician, the indications of an inebriate diathesis were clear Nothing could be more fatal than the alcohol prescription These two cases appear to the general physician as simply, one, of nervous prostration and general exhaustion, the other, a hypochondriac with disturbed intellect and emotions Had a careful history of each been made the contra-indicative symptoms would have been apparent The general rule may be laid down that all cases of physical and mental exhaustion are extremely susceptible to the poisoning of alcohol, and liable to take on diseased conditions that are more or less permanent from its use 2 From the best authority of clinical observers in this country and Europe, the use of alcohol in the sick room is attended with great danger, unless judiciously used 3 The conditions contra-indicating its use are numerous and should be studied carefully where alcohol is thought to be of value 4 The value of alcohol as a medicine is not assured beyond all question, the evidence upon which it has been given will not stand the test of analysis or accurate clinical observation, and we should always be well assured of the diagnosis of the case, and have strong evidence sustaining its use as a medicine, in a given case

ON THE UNITY AND NATURE OF MORBIFIC POISON

BY GEO J ZIEGLER, M D , OF PHILADELPHIA

In the number of this journal for Dec 20, 1884, Dr G Frank Lydston, of Chicago, presented an interesting summary of the generalization of Dr G de Gorrequer Griffith, of England, "On the Unity of Poison in Scarlet, Typhoid and Puerperal Fevers, Erysipelas, Diphtheria, Sore Throats, Certain forms of Diarrhœa and Allied Affections, Pleurisy, Pneumonia, Pleuro Pneumonia, and many other Ailments usually considered to be separate and entirely distinct Diseases," in which the author states that "by unity is meant not that the poison is always the same, but that one poison—the one *origo mali*—whatever it may be, will originate several so called different affections, moreover, "that these ailments may be generated *de novo*, and from one common cause," as well as secondarily by contagion

But, while it is thus recognized that there is one common poison or basic cause for a large number of apparently diverse diseases, the precise nature of this primal poison is acknowledged to be undetermined by, and unknown to, the author

Now, this theory of the unity of cause and spontaneous origin of such diseases is of much more comprehensive application than is here given it, and is supported by reason, observation and experience, as well as exemplified in chemistry, physiology, etiology, pathology, hygiene and therapeutics, being also in direct conformity with the laws of nature in general Long since I arrived at the conclusion that there was *one common pathogenic factor or underlying* morbific principle of a great variety of apparently distinct diseases, and that all the varied so called scorbutic, necræmic, zymotic, septic, contagious, infectious, mephitic, putrescent, and allied diseases, by whatever name designated, are dependent upon one and the same basic *materies morbi* Moreover, observation and experience taught me that this primal poison and morbific factor from which all others originate, is of an alkaline nature, and finally, investigation convinced me that this general *fons et origo mali* and basic pathogenic principle is the well-known volatile organic alkali—*Ammonia*, that is spontaneously engendered within, as well as without the vital organism, which is frequently surcharged therewith from either or both intrinsic and extraneous sources Furthermore, that while the fixed alkalies—soda and potassa—in excess, induce a similar scorbutic state of the system, the primal poison and general basic pathogenic factor of all such maladies, and, in fact, the common underlying, complicating and malignant element of all diseases—local as well as systemic—is this omnipresent, noxious, volatile organic alkali—ammonia

Thus, the superalkalinity from an excess of ammonia in the animal organism induces a scorbutic, toxæmic, typhohæmic, septic, infectious, phlogistic, pyæmic and deliquescent dyscrasiæ, with concomitant necræmic, uræmic, lithæmic, zymotic, phlegmonous, febrile, suppurative, microbic, contagious, mephitic, colliquative, and disorganizing sequelæ, of a varied character and complexity, according to the quantity or degree of activity of this virulent agent in the economy, and special favoring influences of climate, season, weather, exposure, occupation, ingesta, tendencies and conditions of system, habits and modes of living, pestilential and other morbific agencies, which are manifested in diverse diseases, as malarial, yellow, ship, typhus, enteric, puerperal, and other malignant and low fevers, with variola, scarlatina, cynanche, diphtheria, measles, eczema, cholera in its various forms, diarrhœal, leucorrhœal, albuminous, serous, hæmorrhæal, purpuric, purulent, and sanious defluxions, erysipelas anthrax, carbunculoid, gangrenous, contagious, scorbutic, mephitic, putrescent, and colliquative diseases and complications generally—both constitutional and local Hence, while this primal *fons et origo mali* and basic morbific agent—ammonia—is always the same, the secondary and complicating poisons, contagious principles, microbes, pathogenic influences, morbid conditions and diseases may vary indefinitely

Thus, by a process of evolution from the constituent elements and basic principle of ammonia within as well as without the vital economy, varied noxious agents, poisons, ptomaines, contagia, microbes, and diseases of a scorbutic, purpuric, toxæmic, zymotic, septic, phlogistic, febrile, pyæmic, purulent, infectious, malignant, mephitic, colliquative, gangrenous, disorganizing, and adynamic character, are spontaneously as well as secondarily developed in the living body, in like manner as the multifarious plants—microscopic and macroscopic—or forms of life and organic substances—both noxious and innocuous, are produced in the earth from the same elemental principles, *according to season, weather, temperature,* moisture, or climatic, meteorological, and other favoring conditions, ammonia, with carbonic acid and water, affording the essential elements or basic material for the development of toxic and morbific agents, microzymes, disease, and decomposition *within as well as without the animal organism*

Hence, as all these varied manifestations, toxic principles, conditions, microbes, and maladies depend upon the same general agent and basic pathogenic factor of an alkaline and ammoniacal nature, it naturally and logically indicates the correct counteracting and true remedies or specific treatment therefor—both preventive and curative—which are of an acid, antialkaline, antiscorbutic, antizymotic, antiseptic, germicidal, disinfectant, resolvent, depurative and corroborant character, as practically demonstrated by sanitary, hygienic and therapeutic measures, from both empirical and scientific observation and experience, proof of which, with the special articles, forms, varieties, properties, combinations, and applications of protective and remedial agencies therein, I have presented in my recent work on "The Basic Pathology and Specific Treatment of Diphtheria, Typhoid, Choleraic, Zymotic, Septic, Scorbutic, and Putrescent Diseases" generally

January 30, 1885

MECHANICS OF THE V LEVER BRACE IN POTT'S DISEASE

BY C E WEBSTER, M D , CHICAGO, ILL

THE MECHANICS

My attention has several times been attracted by discriptions of this apparatus The paper recently published in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION so fully sets forth its construction and mode of application that a discussion of its mechanics may not be out of order

As described by the author, Dr Charles F Stillman, of New York, the apparatus acts upon the principle of a spring lever posterior splint How does it differ from the older application of this same principle?

FIG. 1.

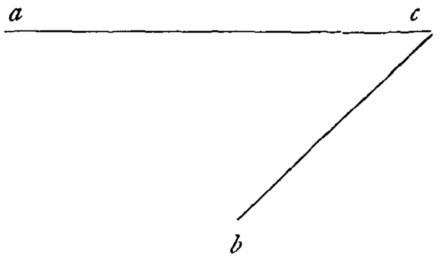

FIG. 2.

Let Fig. 1 represent the new apparatus and Fig. 2 the old. We will first consider its application as a lever. Traction is exerted on the ends of the spine, at *a* and *c*, pressure applied to the point of curvature, at *b*. As in each instance *b* is the fulcrum of the lever, the pressure at that point will equal the sum of the forces applied at *a* and *c*, therefore, as levers, we see that the two appliances are identical.

As springs, they differ materially. In Fig. 1 the spring is *a, c, b,* which is longer than *a c* the spring in Fig. 2. If the same sized rods were employed for each spring, in order to exert a given force at *b*, greater displacement of the points *a* and *c* of Fig. 1 would be necessary than of Fig. 2, for the longer rod would be more flexible.

This difficulty is overcome in the new apparatus by making the angle *a, c, b* adjustable, thus permitting any desired amount of displacement of the ends *a* and *c*. In the old apparatus, this adjustment of the ends of the spring can only be accomplished by bending the rod *a c* in a direction contrary to the curves of the spine. It is not so convenient but an equally efficient mode of making the necessary pressure.

In the older appliances the spring being short, any yielding of the spine at the point of curvature would cause a greater relaxation of the spring than in the new. For this reason, the old apparatus requires closer supervision by the surgeon than the new, and the new apparatus is more likely, in the hands of careless surgeons and instrument makers, to produce cordosis. There is no new principle applied in this instrument; it is simply a new application of an old principle, much used in spinal braces. As such, its range of usefulness can best be determined by a practical test.

MEDICAL PROGRESS.

MATERIA MEDICA AND THERAPEUTICS.

SALICYLIC ACID FOR CORNS.—M. Pierre Vigier (*Gazette Hebd. Med. Times*) observes that there have been for some time past sold in the shops various applications for corns under the most fantastic names, but of undoubted utility. Their authors have profited by the remarkable properties of salicylic acid, fixing it by means of collodion, and which, applied to the skin, produces a solid varnish, and causes neither pain nor other inconvenience. He has examined all these secret preparations, and believes that the following formula is a correct representation of their composition: Salicylic acid, 1 gramme, alcoholic extract of cannabis sativæ, ½ a gramme, alcohol, at 90°, 1 gramme, ether, at 62°, 2½ grammes, and elastic collodion, 5 grammes. Mix *secundum artem* and keep in a stoppered bottle. This is applied by passing over the corn several times a little brush, or the end of a match, which has been dipped in the liquid. This is repeated every other day for a week, and some days later the corn may be easily removed under pressure of the finger, or after a foot-bath.

SURGERY.

OSSEOUS FORMATION OF THE DURA MATER.—Dr. C. W. Morgan gives, in the *Australasian Medical Gazette*, the case of a West Indian black who went on a drunk, the effects of which kept him in bed for several days in a "sulky" condition, he neither eating, drinking, nor speaking to any one. On the fourth day the doctor saw him, when his case presented the following symptoms: Head thrown backwards and to the *left* side, teeth clenched, muscles of the jaw rigid, *left* sternomastoid in a state of chronic contraction, risus sardonicus of face affecting the *left* side only, eyes fixed and staring to the *left*, pupils sensitive to light, *right* arm semiflexed and rigid, ulceration of lower lip, no power of deglutition. Two days later condition much the same, a slight swelling is observable on the anterior surface of the right parietal bone, like an incipient "puffy tumor" as described by Pott. This tumor became more marked later in the history, was slightly painful when touched, causing the patient to flinch. From the eleventh to the fourteenth day he suffered from slight epileptic fits. He became comotose and died on the sixteenth day of his illness.

Dr. Morgan diagnosticated the existence of mischief immediately under the swelling inducing separation of the dura mater, but considered that to use the trephine would be running too great a risk. Post-mortem.—No external marks of injury to the head. On reflecting scalp a patch of ecchymosis observable under the "puffy tumor" above described. Pericranium non-adherent, and the surface of the cranium darkened and dusky-red in color in this situation. Calvarium removed and exhibits a discolored patch about the size of a five shilling piece, on its internal table, corresponding to the outward discoloration. Dura mater exhibits same appearance of dark patch, at the lower end of which there is a perforation leading to a cavity, in the interior of which is to be perceived growing from the inner surface of the *dura mater* a spiculated irregular shaped piece of bony deposit; the cavity containing no fluid nor matter. On the right side of the *falx cerebri* there is also a bony plate, somewhat like a small limpet shell, and also an irregular spiculated piece of bone. These are on the same plane with and adjacent to the cavity above described. The vessels of the brain were not congested, the ventricles contained a little fluid, probably post-mortem, the substance of the brain was soft and degenerative

THE THYROID GLAND IN ITS RELATIONS TO MYXŒDEMA, CRETINISM, GENERAL NUTRITION, AND SURGICAL TREATMENT —Mr Horsley has recently delivered two lectures on this subject, embodying the results of his experiments on monkeys, a brief of which appears in the *Medical Times* Mr Horsley supports the view which was first clearly formulated by Dr Felix Lemon, that cretinism congenital or acquired, myxœdema and cachexia strumapriva, are one and the same condition, and are closely related to this gland and the question of its removal The thyroid must be considered to be a gland from its structure It is bilobed, encapsuled, having its substance divided by trabeculæ of connective tissue which form a stroma with large alveolar spaces Running in the course of these trabeculæ are very numerous and large blood vessels and lymphatics, which latter form large lacunar spaces immediately outside the margins of the alveoli The nerves have at present been associated in function with the vaso-motor system Anatomical proof is yet wanting of the intercommunication of the acini, in an early stage they are composed of columnar epithelium, which later becomes cubical Their walls are surrounded by a rich capillary network, while their lamina contain a glairy fluid allied to mucin

After thyroidectomy the subject of the ablation becomes cretinous, dogs become idiotic and die comatose, monkeys assume the condition called myxœdema, which Mr Horsley believes to be one stage in a general and profound change occurring in the nutritive processes of the human frame, consequent upon the removal of the thyroid

Mr Horsley proceeds to give the details of the operation, post-mortem evidences in which show that in no case were the recurrent laryngeals or the sympathetic trunks injured, a fact which goes far to disprove the theory that myxœdema is a primary disease in, or injury to, a sympathetic nerve, then follows with the symptoms and post-mortem results, from which he formulates his facts to guide as accurately as possible to the ultimate elaboration of a theory as to the true pathology of myxœdema

1 Anatomical

(A) The thyroid appears to consist of two portions (1) a glandular, consisting of highly vascular acini, which excrete a mucoid substance—a mucin-excreting portion? and (2) highly vascular lymphoid nodules—hæmatogenous function?

(B) Excision of the gland is followed by a great increase in the quantity of mucin found in the tissues, an increased activity of the mucin-producing glands, and a change in function of other non muciparous glands whereby they become mucin-formers

(C) Profound changes also ensue in the blood The red corpuscles are decreased with leucocytosis, the coagulability is lessened, and its albumins are altered in character

(D) Nerve symptoms also appear, changes taking place in the lowest motor centres, causing rigidity, tremors, and paresis Changes occur in the higher psychological centres, whereby imbecility and cretinism occur, followed by death, which usually occurs in a condition of coma

Reviewing these facts, Mr Horsley points out that it is clearly shown that removal or alteration of the function of the thyroid is the cause of the general bodily condition Whether such changes may be due to the intermediate action of the vaso-motor or a trophic centre, it is impossible to say May not the thyroid be an excreting gland, the removal of which, as is usual in analogous cases, induces death? In support of this, it is urged that removal of one lobe causes hypertrophy of the other If subsequently the second lobe be removed, myxœdematous symptoms arise

The conditions demanding surgical treatment are (1) Hypertrophy or adenoma, with or without some amount of cystic degeneration or fibroid overgrowth, (2) cystic disease, (3) malignant new growth In this last case, only removal of the gland can be of any avail Adenoma occurs as exophthalmic and simple goitre The former has been relieved, it is said, by total or complete removal, and this treatment seems to hold out most chance of benefit Injection and removal are the two modes of treating simple goitre Injection with laceration of tissue, is very dangerous, as secondary inflammation may arise Simple injection has caused sudden death by the injection of the iodine into a vein, and the iodine travelling to the heart and causing thrombosis It is advisable to wait before injecting, to see by the flow of blood whether a vein has been wounded Excision of the thyroid as a whole, it is said, is absolutely unjustifiable, especially as excision of a part causes the goitre to shrink Mr Sydney Jones removes the isthmus between silk ligatures, and obtains good results

MEDICINE.

A METHOD BY WHICH ONE CAN SEE THE SHADOWS OF ONE'S OWN RETINAL VESSELS AND YELLOW SPOT —Dr W Odillo Maher, in the *Australasian Medical Gazette*, gives what he considers a better method than the well known one of Purkinje, for this purpose Standing at some distance (ten feet) from a lighted gas jet in an otherwise darkened room, and covering one eye, say the left, with the left hand, the observer takes between the forefinger and thumb of the right a strong convex lens and holds it at about its focal distance in front of the right eye Then, steadily gazing at the light through the centre of the lens, he shakes the lens rapidly backwards and forwards along its axis, or up and down, or from side to side After a few seconds the shadow of the forea centralis appears in the axis of vision as a light yellow patch studded with dark coarse granules Simultaneously the retinal vessels in the region of the yellow spot, including the finest capillaries, appear as dark cords against the yellow light The outline of the shadow of the forea centralis, which falls upon the most sensitive part of the retina, the yellow spot, is well defined, while the outline of the shadow of the optic disc cannot be distinctly seen, as it falls upon a much less sensitive part of the fundus The shorter and more rapid the movements of the lens the sooner the shadows of the retinal vessels and forea centralis appear, and the more distinctly are they seen

The main points of difference between this and Purkinje's method are

1st That the rays of light are not thrown obliquely on the sclerotic or cornea, but are directed along the visual axis, and consequently fall perpendicularly on the surface of the cornea

2d The image of the retinal vessels is not projected on a dark wall, but is seen against the yellow light

3d The shadow of the forea centralis is faint and difficult to recognize by Purkinje's method, whereas by this method it is as clearly defined and as easily seen as the shadow of the retinal vessels

ELECTRICAL NEUROSIS —M Fere (*Progres Medical, Med Times*) records the case of a woman, aged 29, who had exhibited various nervous symptoms, including well marked ovarian hyperæsthesia, had for two years presented the remarkable phenomena about to be mentioned She noticed that her fingers attracted bodies, such as pieces of paper, ribbons, etc , and her hair not only gave sparks when in contact with the comb, but had become very unruly in the matter of lying smooth When her linen came near her body a flash of light was produced, and her clothing adhered closely to her body, so much so sometimes as to interfere with the freedom of her movements These phenomena were more marked under the influence of strong emotions, and were lessened in damp weather, so that she was able to foretell what the weather was going to be like, from the increase or diminution in her state of electric tension The patient was thin and anæmic, and subject, especially in damp weather, to œdema of the legs With a view to prevent this loss of electricity, she was recommended to wear silk next to her skin, which was further powdered all over with lycopodium, but without much benefit Subsequently the daily application of static electricity, by means of an electric bath for about ten minutes, was followed by good results This fact confirmed M Fere in his idea that this was a case not of exaggerated production of electricity, but rather of an abnormal loss of it, probably owing to the dryness of the skin

THE DIAGNOSTIC VALUE OF CLINICAL METHODS USED TO DETERMINE THE PRESENCE OF ACID IN THE GASTRIC JUICE —Dr Dujardin-Beaumetz discusses this subject in the *Gaz Hebd de Med et de Chir* The Germans consider that an important point in the diagnosis of cancer of the stomach may be determined by the modifications produced by this disease in the acidity and digestive power of the gastric juice Leube, following the experience of Vanden Velden, holds that one of the first effects of the production of carcinomatous neoplasms in the walls of the stomach is to diminish the quantity of hydrochloric acid contained in the gastric juice To determine this fact three methods are made use of—that of washing out the stomach, the use of the sponge, and the use of the stomach explorer In washing out the stomach, the patient fasting, Leube introduces by means of the stomach sound 300 cubic centimetres of water at zero C He allows the fluid to remain a half hour, and then removes it by siphoning the stomach, using his reagents to determine its characteristics The use of the sponge is more common, and Dr Dujardin-Beaumetz tells us that most of the patients who go to Carlsbad for stomach affections are submitted to this examination before being permitted to drink the waters A small piece of sponge is covered by a thin layer of gum, provided with a thread of silk, swallowed by the patient, and pulled out again by the thread at the end of half an hour, the contained liquid is pressed out for examination In France they cover the sponge with a capsule before it is swallowed This method is not without its inconveniences, it is often very difficult to swallow the sponge, the presence of the thread in the pharynx excites vomiting, it is difficult to be positive as to whether the sponge has passed into the stomach or remains in the œsophagus, and finally but a very small quantity of liquid is obtained To remedy these defects Dr Dujardin-Beaumetz has prepared what he calls the gastric explorer, which consists of a resisting but flexible stomach tube, in the interior of which he places a glass reservoir whose lower extremity is provided with a small rubber tube extending beyond the end of the sound and thus placing the reservoir in connection with the mucous membrane of the stomach, its upper extremity is provided with a much larger rubber tube passing out of the superior end of the siphon and leading by means of a bit of glass tubing to a rubber bag, silken threads attached to the reservoir allow of its removal Its use is very simple it is introduced into the stomach of the fasting patient, and a vacuum produced by pressing upon the rubber bag, when the pressure is relieved the fluid contents of the stomach pass up and the fact is further indicated by inspection of the glass tube connecting the rubber tubing and bag Once removed, pressure upon the bag will discharge the liquid into the vessel prepared to receive it for examination

To recognize the acidity of the gastric juice in Germany, *tropocoline* is used, one of the coloring matters of the products of coal tar In France an analogous substance under the name of Poirier orange, from the house which prepares it, is substituted In commerce there are three varieties of tropocoline, viz zero, double zero, triple zero The tropocoline double zero is the one used, and is a yellow powder which, dissolved in water, gives a yellow color When these coloring matters are brought in contact with an acid, and especially hydrochloric acid, a handsome violet red color results Lactic acid gives an orange-red, a distinction which is easily recognizable This test renders it easy, from the degree of intensity of color produced, to determine the degree of acidity present To apply the test the fluid is filtered and placed on a watch-glass which rests on a white surface, and with the aid of a dropper, a solution (1 100) of the test is applied in drops until the color is apparent Leube continues his examination by submitting little cubes of albumen of a determined weight to the action of the liquid in a stove kept at the temperature of 40° C , watching the artificial digestion and comparing it with that in a given quantity of pepsin and hydrochloric acid

As to the diagnostic value of these methods, Dr Dujardin Beaumetz is in very great doubt It is questionable as to whether hydrochloric acid is secreted in the fasting stomach, where food remains in the stomach other acids, such as lactic, butyric and propionic acids, develop as the result of numerous fermentations In his own experience he has frequently obtained doubtful results from uncertain colorations Certain important physiological facts certainly result from this method, as in positively determining the acid dyspepsia of drunkards Leube concludes that these facts establish the presence of a tenacious and decided dyspepsia, but does this warrant the complicated method?

A NEW SYMPTOM OF LEAD POISONING —M Du Moulin has recently presented to the Brussells Academy of Medicine (*Rev de Therep*), a young man who five days previously was attacked with lead colic, but who no longer presented any apparent sign of lead poisoning, other than the blue line on the gums He called attention to a very curious and new pathognomonic symptom which frequently appeared before the blue line of the gums, always accompanied it, and is more characteristic and better demonstrated than the other This symptom manifests itself by the formation in the epidermis of a frequently very abundant deposit of sulphate of lead By the application of an alkaline sulphate he had traced black lines all over the body of the subject presented The reagent by the use of which he had inscribed the chemical symbol of lead (Pb) on the chest, on the back and on the flanks of the subject, was a solution of monosulphuret of sodium, in the proportion 5 per cent, in distilled water The sulphydrate of ammonia produced the same effect He gave his experience as follows

1 The skin of all persons affected with lead poisoning, so far as he had examined them, to the number of 14, contained lead in sufficient quantity to react directly upon the contact of a glass rod dipped in a solution of monosulphuret of sodium at 5 per cent

2 In recent cases this reaction is much stronger than in older cases

3 Washing with cold or hot water does no more than to remove a few epidermal scales containing lead, the limpid filtered liquid contains no lead in a soluble state

4 Prolonged washing with tartrate of ammonia removes from the skin this property of blackening by the sulphuret of sodium The water used contains all the lead in the form of a sulphate rendered soluble by the tartrate

5 The sulphuret of ammonia and the monosulphuret of sodium precipitate a considerable quantity of lead, in the form of the sulphuret

6 The surface washed by the tartrate of ammonia no longer reacts with the sulphuret of sodium, the deposit then which exists upon and in the epidermis is exclusively formed of sulphate of lead

7 Those parts of the body, which from the prolonged washing with tartrate of ammonia no longer react with the sulphuret, resume this characteristic at the end of a few days

8 The reaction, which is not very apparent at the end of one or two days, increases daily

9 The sulphate of lead then passes to the skin and becomes fixed there through the agency of the cutaneous secretion , but we are still ignorant of how that body, so insoluble in its nature, is carried there and becomes so fixed

ON DIPHTHERITIC ALBUMINURIA —Dr Cadet de Gassicourt (*Revue Mensuelle des Maladies de l'Enfance*, *Med Chronicle*) gives the result of his observations on eighty five cases of diphtheria in the Hopital Trousseau, in Paris The cases included diphtheria of the pharynx, larynx, or other parts, some being mild, others malignant Of these eighty-five cases sixty-three, or 75 per cent , had albuminous urine He divides his cases into four groups

1st Of twenty-two cases in which there was no albumen in the urine, twelve recovered and ten died

2nd Of twenty nine cases in which there was only a faint cloud of albumen, twelve recovered and seventeen died

3rd Of nineteen cases in which the amount of albumen varied from 025 to 1 per cent , eight recovered and eleven died

4th Of sixteen cases in which the amount varied from 1 to 1 5 per cent , three recovered and thirteen died

The author arrives at the following conclusions

1 The presence or absence of albumen is of much more prognostic importance in pharyngeal diphtheria than in croup

2 The absence of albuminuria in diphtheria indicates that it is of a milder nature than where albuminuria is present In croup it has no such signification

3 The presence of a small quantity of albumen (below 1 per cent) has no special signification, where it is above this amount the prognosis is extremely serious, but not certainly fatal

4 The amount of albumen indicates the intensity of the general toxæmia

RELATIVE DIGESTIBILITY OF FISH FLESH IN GASTRIC JUICE —Messrs R H Chittenden and Geo W Cummins have been making some extensive experiments upon this subject in the *Sheffield Laboratory of Yale College*, which they have published in detail and in tabulated form in the *American Chemical Journal* Their results show that the average digestibility of fish flesh is far below that of beef similarly cooked In but two instances, in the case of shad and lake white, does the digestibility of fish flesh approach that of beef, although, from the average of the experiments, several are as easily digestible as mutton, lamb and chicken They find the average digestibility of the salmon and trout to be considerably below the average of the more digestible white fish The difference between the digestibility of the light and dark meat of the same fish is somewhat striking, as in the case of the shad, where the digestibility of the former was found to be 97 25, as compared with beef, while the dark flesh was 87 32 This difference in digestibility is in part due, without doubt, to the amount of fat present, for in the flesh of white fish there is but little fat, it being accumulated mainly in the liver of the animal, while in red fish there is more or less fatty matter incorporated with the muscular fibres Eels and herring in digestibility stand below the more digestible white fish, mackerel, however, from a single experiment with the white portion of the flesh, showed a comparatively high digestibility In all of these experiments, however, with white fish, the outer layer of dark flesh was rejected, except in the case of the shad The varying differences in digestibility are not to be considered as due wholly to differences in the amount of fat in the flesh, thus the flesh of fresh cod contains but little fat, and yet it is one of the most indigestible of the white fish experimented with

With regard to the difference in digestibility of raw and cooked flesh, these observers arrived at the following results with a gastric juice containing but 0 2 per cent of pure hydrochloric acid

	Beef Raw	Beef Cooked (Steamed)
Amount digested from 20 grams	4 0792	3 8610
Relative proportion,	100 0	94 65

	Blue Fish Raw	Blue Fish Cooked (steamed)
Amount digested from 20 grams	3 7617	3,5885
Relative proportion,	100 0	95 39

It is plain then that the raw flesh in its digestibility is considerably greater than when cooked In some instances, at least, the flesh of younger animals is less easily digestible than that of older animals of the same species

AN ASCARIS LUMBRICOIDES EXTRACTED FROM THE UMBILICUS —Dr Donald Macphail presented the specimen and gave the history of a case of this character before the Glasgow Pathological and Clinical Society (Glasgow *Medical Journal*) The patient, a boy four years of age, enjoyed good health until about five months before (he had been successfully treated for thread-worms), when he became listless, cross and restless, and suffered from severe diarrhœa, belly became swollen and tender, began to emaciate, and had a slight attack of scarlet fever Belly protuberant and tense, superficial veins much enlarged Could bear firm palpation without much pain Percussion dull and tympanitic, a suspicion of fluctuation at the most dependent parts of the abdomen Weak, emaciated, apathetic, took but little food, occasional attacks of very severe diarrhœa, profuse night sweats, pulse quick, small and thready, but regular, respiration easy There supervened upon these symptoms a slight discharge, which in time became abundant, of thin watery pus from the umbilicus, with very offensive but not fæcal odor This discharge caused painful excoriation of the surrounding skin Later he suffered considerable pain and difficulty in micturition, especially at the beginning of the act, which produced marked retraction of the testicles Between the umbilicus and pubes there developed a diffuse, slightly elevated swelling, which was very tender to the touch, but without any redness of the skin On the day of the discharge of the lumbricoid he became apparently moribund with, for the first time, considerable œdema of the feet and legs That evening he suddenly called out that his "belly was dirty" On examination there was found protruding from the umbilicus about two inches of a round worm, wriggling actively Without difficulty his mother drew out the worm, which was about nine inches long From that time there was rapid improvement

In the discussion which followed, Mr Maylard thought that a very possible explanation of the condition was a patency of the vitello-intestinal duct It is known that a communication sometimes exists between the umbilicus and the ileum through a permanency of this fœtal connection, and it is not unlikely that the worm may have thus made its way to the umbilicus, excited inflammation, and then escaped

RESTORATION OF NATURAL COLOR OF HAIR — Vandeleur C Isdell (*Medical Times*) gives an account of the case of his father who, in 1861, when 62 years of age, was completely gray in the hair of his head and beard, whereas, in 1882, that is to say, 22 years later, when he died at the age of 83, the hair of his head was of its original natural dark color, the whole of it being quite dark with the single exception of a few gray hairs on each temple He had for many years kept his beard shaved off, so the change in it could not be noted

DR F H BOSWORTH reports, in the *Medical Record*, that on applying a two per cent solution of cocaine to the nasal passages, the venous sinuses below the mucous membrane become, within twenty or thirty seconds, so rigidly contracted as to expel all the blood contained in them, and to cause the membrane to cling closely to the bony structure which then becomes sharply outlined He has used the drug in hypertrophy of the nasal mucous membrane (*nasal catarrh*) acute *coryza* and in operations for nasal *polypus* In each case the venous congestion or turgescence was so thoroughly kept down that all discomfort was removed, and in the case of polypi not only the recognition and removal of the growth became quite easy, but also turned out a bloodless operation

ACNE is often reflex from urethra irritation Dr S Sherwell obtained marvelous improvement in the faces of two patients, after long treatment had failed, by passing cold sounds every third day The urethra was found sensitive, especially at about the junction of the membranous portion with the prostatic —*Jour C and V Dis*

A NEW METHOD OF TREATING PULMONARY COMPLAINTS —Diseases of the lungs have long been treated by the inhalation of condensed or rarefied air Waldenberg, of Berlin, was one of the pioneers in this direction, and his apparatus, or some modification of it, by which patients are made to inspire condensed air, is largely used in Germany At various health resorts —notably, Reichenhall—pneumatic cabinets have been erected with a view to completely immersing the patient in a condensed atmosphere Reports concerning the efficacy of such contrivances are somewhat conflicting, except in cases of vesicular emphysema and chronic bronchitis, where great benefit is often derived The physiological effects of such treatment are pretty well understood, and are recognized to be essentially the same as those of a prolonged and forcible inspiration of air at ordinary pressure Indeed, to supply condensed air, or in other words, air at an increased pressure, to an individual incapable of respiring effectively, is but to supplement or augment his inadequate inspiratory efforts In consequence of an increase in the amount of tidal air inspired, the lungs are more fully expanded, a larger proportion of residual air is displaced, supplanted by fresh air, and by reason of a more vigorous expiration, offending substances are dislodged and expelled As a result of the fuller expansion of the chest, a larger amount of blood is supplied to the right heart and thence thrown into the pulmonary arteries Hæmatosis is furthered, and the nutrition, not only of the lungs, but of the entire organism, is improved Such, in the main, are the advantages secured by this mode of treatment In cases of emphysema of the lungs, German therapeutists claim great benefit may be obtained by having the patient expire into a chamber of rarefied air In this way the lungs are more fully emptied of air and dilated vesicles are allowed to collapse and thus aided in regaining their elasticity In contrast to these methods is another which Dr Herbert F Williams, of Brooklyn, has been employing for the past year and a half with the most encouraging results His interesting report, entitled "Antiseptic Treatment of Pulmonary Disease by Means of Pneumatic Differentiation," appears in the *New York Medical Record* of Jan 17, of the current year This treatment consists in lowering the pressure of the atmosphere upon the body of the patient, while at the same time the lungs are supplied with medicated air at ordinary pressure To accomplish this a cabinet, "The Pneumatic Differentiator," is used, which is provided with an air-chamber By exhausting the air in this latter and allowing more or less of that within the cabinet to pass into the chamber, atmospheric pressure within the cabinet is reduced to any degree desired, as shown by a barometer The degree of rarefaction employed ranges from a barometric fall of one-tenth of an inch to two inches, and corresponds to an altitude of from one hundred to two thousand feet The patient sits in this rarefied atmosphere, yet breathes air conducted to him from outside In order to render his respiration as vigorous as possible, by preventing the escape of air through the nostrils, these are kept closed Furthermore the air inspired is impregnated with any desired medicament

It is evident that this is practically but another method of administering condensed air, and must achieve the same results In consequence of the lowered atmospheric pressure upon the chest walls, these do not assume a permanent inspiratory expansion, but are probably enabled to expand more fully, as likewise do the lungs In other words, as less resistance is offered to inspired air, its pressure becomes relatively increased thereby, which is equivalent to the inhalation of air at originally higher pressure, *i e*, condensed air Moreover, Dr Williams is of the opinion that the vigor and effectiveness of expiration are augmented If so, this is in effect the same as expiring into a rarefied atmosphere

Dr Williams recognizes the benefit due to the deepened inspiration and forcible expiration thus obtained, in expelling secretions, dilating collapsed lobules, etc Nevertheless, he appears to find the chief advantage of this method in the readiness with which medicaments may be applied to pulmonary tissues "Under given conditions of temperature," he says, "air at normal density affords its best vapor-carrying capacity" and subjected to the pressure of a powerful expiratory effort, it "must condense" and deposit the remedial agent upon the internal lung surfaces. That medication may be thus produced, and the results of such topical applications be most happy, we will not dispute, but reserve opinion until further observations afford definite *data*. Yet, when he expresses the hope that a one-thousandth solution of corrosive sublimate or a one per cent solution of carbolic acid will destroy the tubercle bacilli, we venture to remind him of the investigation of Schill and Fischer. These observers found that even a two per cent solution of the bichloride was powerless to destroy the bacilli in question, and that of carbolic acid very strong solutions (five per cent) were necessary. We believe the Doctor must look for the beneficial action of the solutions he employed to some other virtue than that of antisepsis. However, that most encouraging results were obtained by "Pneumatic Differentiation" is undeniable. The total number of cases treated was sixty-two, with thirty-four-recoveries, ten improvements, seven non improvements, eleven deaths. Two cases of nervous cough were not improved. Twenty cases of bronchitis recovered, three of unresolved pneumonia recovered, as did six out of seven cases of primary infiltration, the other being benefited. Of nine cases of acute catarrhal phthisis four recovered, one improved, two did not improve and two died. Two of chronic catarrhal phthisis died; of nine of chronic fibrous phthisis eight were improved, one not; five cases of chronic tubercular phthisis died, one case of tubercular pleurisy and one of laryngeal phthisis were not improved. One of abscess of the lung recovered. One of hæmorrhagic phthisis and one of atrophy of the lung died. As might be expected, phthisical patients were the least benefited though some certainly showed marked temporary amelioration of symptoms with prolongation of life. Five cases of acute tuberculosis are detailed, in which almost miraculous results followed this treatment. The author classes them as cured. The disease was certainly arrested and put in abeyance, but we should hardly like at this early date to call them cured. Space forbids further discussion of them, and hence we recommend their careful perusal to our readers as narrated in the *Record*. We are likewise compelled to refer the reader to the original article for particulars as to the degree of rarefaction, its equivalent in altitude, number of treatments and other interesting *data*. We are pleased to learn that Dr. A. S. Houghton, of Milwaukee, has been furnished with a cabinet, and we hope he will soon be in position to supply us with additional facts.

The influence of "Pneumatic Differentiation" upon the circulation is to be discussed in a paper by Dr. Tiegel. The field thus opened appears to give promise of a rich harvest, and we trust other practitioners will cultivate it.

MEDICAL LEGISLATION.—This being the season of the year when the legislatures of the several States are generally in session, we notice before many of these legislative bodies bills or forms of laws designed for regulating the practice of medicine and surgery. A large proportion of these bills have been prepared and recommended by some medical society or professional organization. We have been interested in examining the details of such of these proposed laws as have come directly under our observation, and we regret to state that most of them bear evidence of having been framed with far more reference to the avoidance of popular prejudices, or the reconciling of medical factions and supposed conflicting interests, than to any sound principles of legislation or of political economy.

For instance, in the bill before the legislature of the State of Texas, we find the following provisions:

SECTION 1. *Be it enacted by the Legislature of the State of Texas*. That there shall be appointed by the Governor, within twenty days after the passage of this act, a State Board of Medical Examiners in this State, consisting of nine reputable physicians, who shall be graduates of legally chartered medical colleges, and who have practiced medicine or surgery for not less than ten years, but none of whom shall be connected in any manner with any medical school or college.

SECTION 2. The nine members of said Board shall serve for two years each, or until their successors are appointed.

SECTION 4. The said Board, shall, on a day fixed by them in every two years, elect from their own number a President and a Secretary, who shall hold their offices respectively for two years, and until their successors are appointed and enter upon the duties of their offices.

SECTION 5. The said Medical Board shall examine all applicants for license to practice medicine or surgery in this State. They shall meet quarterly, on the second Tuesday in January, April, July and October at Austin, and at such meetings shall faithfully examine all candidates referred to them for that purpose by the President of said Board, and the Secretary shall keep a detailed report in writing of all questions and answers of each examination, together with a separate opinion of each examiner as to the candidate in each case. The examination shall be conducted in writing, except clinical examinations, which may be oral. The President and Secretary of the Board shall have authority to administer oaths, and the Board to take testimony in all matters relating to its duties.

SECTION 6. Such examinations shall be in hygiene, anatomy, physiology, pathology, chemistry, surgery and obstetrics.

SECTION 8. Any person on paying fifteen dollars to the Sec retary of the Board, and on presenting a receipt for the same to, and applying to the President of the Board shall receive an order addressed to the aforesaid Medical Board, instructing them to examine the candidate at the next quarterly examination, providing proof satisfactory to the President is first given, that the candidate is over 21 years of age, of good moral character, and has studied clinical medicine and surgery in hospitals containing not less than fifty beds, and having an average attendance of not less than thirty patients

SECTION 10 The State Board of Medical Examiners shall establish such rules and regulations as they may deem necessary to insure the faithful execution of this act

SECTION 15 Any person who shall practice medicine or surgery in this State without a license, as provided for in this act, shall be guilty of a misdemeanor, and, on conviction thereof, shall be punished by a fine of not less than $100 nor more than $500, for the first offense, and for each subsequent offense by a fine as aforesaid or by imprisonment in the county jail not less than thirty days, nor more than one year, or both at the discretion of the court The fine, when collected, shall be paid to the secretary of the Board, for the benefit of the State Board of Medical Examiners

SECTION 16 For the purposes of this Act, the words "practice of medicine or surgery" shall mean to annex the letters "M D" to one's name, or to suggest, recommend, prescribe, direct or employ, as a matter of business, or for a fee, for the use of any person, any drug, medicine, appliance, apparatus or other agency, whether material or not material, for the cure, relief or palliation of any real or supposed ailment or disease of mind or body, or for the treatment, cure or relief of any wound, fracture or bodily injury, or infirmity or deformity

SECTION 19 The State Board of Medical Examiners shall have the power to strike the name of any practitioner of medicine or surgery, guilty of unprofessional or dishonorable conduct, from the registry list, and to refuse to allow his name to be recorded or to permit him to practice medicine or surgery in this State, upon unanimous vote, after giving the accused an opportunity to be heard in his defense

These are the essential features of the proposed law It simply provides for the appointment by the Governor, of a State Board of Medical Examiners composed of nine practicing physicians with certain qualifications, and with a tenure of office lasting two years, or just about long enough to get acquainted with their duties

They are required to meet four times a year for the examination of all candidates who may present themselves with an order from the President of the Board, certifying that they are entitled to such examination The only conditions required for obtaining the order from the President, are the payment to the Secretary of the Board the sum of fifteen dollars, with proof of being 21 years of age, of good moral character, and of having "studied clinical medicine and surgery in hospitals containing not less than fifty beds, and having an average attendance of not less than thirty patients" Not a word is expressed regarding any standard of general education, nor length of time required for studying medicine and surgery, nor even whether the candidate shall study in the hospitals alluded to, three years or only *three days*

If it be said that these matters are to be regulated by such rules and regulations as the Board may adopt, it can be answered by the fact that the entire Board is liable to be changed every two years, and consequently that the rules and regulations may change just as often

Again, it will be seen that the examinations of the Board are limited to "hygiene, anatomy, physiology, pathology, chemistry, surgery and obstetrics," leaving out entirely materia medica, therapeutics and practical medicine, the three branches of more direct practical importance to the people of the State than all the other branches united By another bill, or separate legislative act, it is proposed to make this same "State Board of Medical Examiners, under the same organization, the State Board of Health," which "shall have general supervision of the interests of the health and life of the citizens of the State" of Texas The same board is also to constitute "the Bureau of Vital Statistics, and to procure such data from all local authorities and health officers throughout the State, as may enable them to prepare an annual report to the Governor on the subject of vital statistics" There is only one thing which actually disqualifies any reputable physician of Texas, who has practiced his profession not less than ten years, from receiving an appointment on this important board, and that is, connection in any way with a medical college The subject of a State Board of Medical Examiners for the State of New York, was reported on by a committee and elicited much discussion, during the recent annual meeting of the old Medical Society of that State Such discussion resulted in a vote recommending the creation of a State Board, composed of nine members, to be appointed annually by the Regents of the State University

Six of the nine members were to be selected from the membership of that Society, three of the six to be also members of medical college faculties, the other three to have no connection with such colleges, while the remaining three members of the Board are to be appointed from the incorporated homœopathic and eclectic State Medical Societies of that State As there are eight or ten incorporated medical colleges in the State of New York, the three members of the State Board to be selected from the faculties of those institutions could directly represent only a small minority of them, and would be regarded with suspicion by all the rest, while the apportionment of the other six members of the Board, to certain incorporated medical societies representing three classes of medical men, or so-called schools of medicine, if enacted into a law, would constitute a direct legal recognition, not only of special factions and isms in medicine, but also of different standards of education for men licensed to pursue the same calling The enactment of such a law would constitute a species of class legislation having no tendency to advance either the science or art of medicine, but strongly tending to perpetuate and foster the several factions and pretended medical systems that are recognized by its provisions As we have said on other occasions, the only legitimate basis on which governments can assume to enact laws for the regulation of the practice of medicine, is the protection of the people from the impositions of ignorance and knavery on the part of those who attempt to practice the healing art And no law will be permanently efficient in affording such protection, that does not make proper provision, first, for the exaction of a fair standard of general education prior to entering upon the study of medicine, second, for a minimum standard of medical attainments, or what shall constitute the necessary curriculum of medical studies to be mastered as a requisite for license to practice, third, for the minimum of time to be devoted to the study of such curriculum, and what proportion of it shall be spent in medical colleges and hospitals, and fourth, for an independent and properly qualified State Board of Examiners, charged with the executive duty of seeing that the three preceding provisions have been faithfully complied with, and by direct personal, impartial and uniform examinations of all candidates alike, grant a license to those only who are found qualified to practice medicine and surgery with safety to the people, without any regard to, or recognition of, special schools or medical factions of any kind Laws for the regulation of medical practice, founded on these principles and including the clearly defined provisions just stated, would greatly aid in the advancement of medical science, in securing a more thoroughly qualified body of medical men, and consequently in benefiting all classes of the people If it be said that public sentiment is not yet sufficiently enlightened to sanction the enactment of such a law, then let us labor and wait until it is, rather than lend our influence to such imperfect enactments as serve no other purpose than to confer a government license upon half a dozen sorts of doctors, by which the whole are leveled downward instead of up

EDITORIAL CHANGES —Dr J Nevins Hyde, who for several years past has been the chief editor of the *Chicago Medical Journal and Examiner*, has retired from that position, and Dr S J Jones has been appointed by the Directors of the Medical Press Association to fill the place Dr Hyde has discharged his editorial duties with decided ability and good judgment, and while we congratulate him on being free from the annoyances and unremitting work incident to editorial life, we sincerely regret his departure from the editorial fraternity We welcome his successor, with the hope that he will find his new field of labor both pleasant and profitable

DR JOHN MONTGOMERY, father of Dr Liston H. Montgomery of this city, died at his residence in Adrian, Seneca county, Ohio, on the 29th of January, 1885, aged 63 years After having acquired a fair literary and professional education, chiefly by his own labor, he entered upon the practice of medicine in 1845, and performed the arduous duties of his calling with a marked degree of fidelity and success until near his death—a period of about forty years After suffering two attacks of pneumonia from which he recovered, laryngeal phthisis was developed apparently from night exposure in the performance of professional duty, from the wasting effects of which he died

OHIO STATE SANITARY ASSOCIATION —The second annual meeting of this organization was held in the Board of Trade room, City Hall, Columbus, Ohio, on the 5th and 6th inst , and was well attended by those interested in the sanitary improvement of the State Dr William Morrow Beach, of London, Ohio, presided and delivered an address on "Epidemic and Contagious Diseases in this Country " A considerable variety of papers of more or less importance were read and discussed, and recommended for publication

THERAPEUTIC GAZETTE —We have received the first number of Vol I , third series, of this valuable monthly journal of physiological and clinical therapeutics It is the first issued under the new editorial management of Drs Horatio C Wood and Robert Meade Smith, of Philadelphia It is filled with matter of interest and practical value

MEDICAL SOCIETY OF LONDON —This is one of the oldest medical societies in Great Britain, having been founded in 1773 At a recent meeting of the Society Dr John V Shoemaker, of Philadelphia, was elected a Fellow

SOCIETY PROCEEDINGS

OBSTETRICAL SOCIETY OF PHILADELPHIA.—STATED MEETING FRIDAY, JAN. 2, 1885.

The president, Richard A Cleemann, M D , in the chair

Double Uterus and Vagina —Dr Wm Goodell described a case which had been sent to him on account of pain in the back, various nervous symptoms and difficult coition The vagina was double throughout its entire length Entrance had apparently been effected indifferently on either side of the septum The cervices were united like the barrel of a double-barrelled gun There was a slight divergence of the upper third of the fundus The sound entered three inches into each cavity The septum vagina was divided up to the cervix, and her physician reports great relief to the general symptoms

Dr C McClelland described a similar case Pregnancy had progressed to the third month, when the case came under his observation The vaginal septum was complete The external contour of the cervix was normal, but a thin septum, extending from the os to the fundus, divided the cavity into two parts The prominence of the uterus was greater on one side of the abdomen The sound was not passed The vaginal septum was divided shortly before labor A living child was delivered About the third day after delivery a mass, apparently of decidua, was thrown off after three or four hours of labor-pains After involution was complete, sounds were introduced into the uterine cavities and the handles diverged one and three-fourths inches A second conception occurred afterward on the other side of the uterus

Dr Goodell some years ago had under his care a case which he at first diagnosticated as an extra-uterine pregnancy, as he apparently found the uterus empty, passing the sound into it, while undoubted signs of pregnancy existed The fœtal tumor was larger toward one side of the abdominal cavity, while the uterus was deflected to the other side He saw the patient every two weeks, and made frequent careful examinations He sent the patient to the university hospital and fixed a day for operation One day while lecturing on the case, he had his hand on the abdomen of the patient and felt a contraction and hardening under his hand This so resembled the action of uterine tissue, that he sent the patient to the Preston Retreat for observation She was delivered spontaneously

There was but one cervix and one os, but there was a uterine septum higher up dividing the cavity into two parts

Dr Harris remarked that the observer in these cases is liable to be deceived, because the enlargement of the uterus causes it to rotate, the empty half of the uterus admitting the sound in the median line The uterus, too, is generally poorly developed, as this form of uterus is probably the result of arrest of development, and its thin walls do not give to the palpating hand, the normal sense of thickness and resistance

Double Ovariotomy with Unusual Complications —Dr W H Parish reported the following case In September, 1884, I saw, in consultation with Dr M O'Hara, a lady who had been under his treatment for a number of months She was 52 years of age and of exemplary habits The menopause had been established for a number of years, and she had enjoyed good health until a few months ago In June, 1884, she noticed for the first time that her abdomen was enlarged In July she consulted Dr O'Hara, narrating symptoms of indigestion In August the abdomen had become so enlarged as to occasion concern on the part of the patient, and she had submitted to an examination by Dr O'Hara About Aug 15th Dr D F Willard saw her in consultation with Dr O'Hara, and the diagnosis of ovarian tumor was coincided in On Sept 6th I saw the patient with Dr O'Hara, and also diagnosticated ovarian tumor The physical signs were the usual ones characteristic of ovarian tumor There was distinct resonance in each flank, and no indication of fluid in the peritoneal cavity The abdominal distension had become very considerable, occasioning no little interference with respiration, and was associated with slight œdema of the lower extremities and general emaciation Removal by operation was urged upon the patient, but was positively refused After the lapse of ten days I again saw her with Dr O'Hara The difficulty in respiration had so greatly increased as to prevent sleep except in the semi-erect position But little nourishment had been taken and exhaustion had correspondingly increased In the erect position the pulse was 160 per minute, in recumbency, 130 The abdomen measured forty five inches at the umbilicus Its shape had changed since my previous visit In the flanks there was distinct bulging, with fluctuation and percussion dullness I diagnosticated peritoneal dropsy as a complication of the ovarian cyst The œdema of the lower extremities had increased The patient had requested that she be tapped, and it was with reluctance that I consented to resort to that measure On Sept 14th, with the assistance of Drs O'Hara and J B Roberts, I attempted to diminish the size of the abdomen by tapping the cyst, using for that purpose the ordinary trocar and canula Only a few drops of thick, gummy substance were obtained The cyst's contents were too thick, too jelly-like, to run through the canula But a single puncture was made The patient now gave her consent to the performance of ovariotomy

Sept 16 The patient has been fed and stimulated as her condition demanded or permitted Pulse 120, resp 40, temp 98¾° F As yet no apparant disturbance from the tapping Sept 17 Pain referred by the patient to the bowels, three movements, probably resulting from indigestion Sept 18 Operation performed, previous to the operation, pulse 130, resp 40, temp 99° F Tongue dry and brown Bowels moved twice during the night Still has pain, supposed by the patient to be in the bowels There were present Drs O'Hara, A H Smith, J B Roberts and McElroy The patient was etherized by Dr Roberts, and the usual incision along the linea alba was made. The tumor was found to be adherent to the anterior abdominal wall. An attempt was made to break up these adhesions, but the cyst wall was so extremely thin that the cyst was soon torn into. Its contents were too gummy to flow, and it was necessary to scoop out this substance with the hand. The contents had the consistence and appearance of calf's-foot jelly and was adhesive like gum, sticking to the hand so that it was necessary to strip it from one hand with the other. There were numerous slight adhesions to the intestines, but as the cyst wall was so extremely thin these adhesions were not troublesome, portions of the cyst wall being left attached to the intestines. It was soon discovered that the cyst wall had ruptured prior to the operation, and that every portion of the peritoneal cavity contained quantities of the colloid material and masses of dark grumous blood. The contents had doubtless escaped gradually from a rent in the upper posterior portion of the cyst several days before the tapping. It was the presence of this material in the peritoneal cavity that led me to diagnosticate the coexistence of peritoneal dropsy. There was no serum in the peritoneal cavity. Washing the peritoneal surface with water would not remove the colloid material, and it became necessary with hand and sponge to remove it from the under surface of the liver, from about the spleen and kidneys as well as from among the intestines. After emptying the large tumor, it was discovered that there was a smaller one about the size of a fœtal head, unbroken and without adhesions and partly pressed into the pelvis by the superincumbent large one. The two tumors presented the same characteristics. They had thin transparent walls with numerous internal alveoli and thin septa, with gummy colloid contents. About the base of each, but especially of the larger, there was a limited amount of solid substance. The pedicle of each was ligated and dropped into the abdomen. Each tumor evidently grew from an ovary. The general peritonium, wherever it could be seen or felt, presented innumerable cysts with walls and contents like those of the ovarian cysts. These peritoneal cysts varied in size from that of a millet seed to that of a pea. Many of the larger ones were ruptured by the hand or sponge. These minute cysts were not arranged in clusters with stem like attachments to the peritoneum, but were isolated and had the appearance of blebs on the peritoneal surface. The peritoneum presented general injection of its capillaries with slight roughening of its surface, but there were no evidences of active or decided peritonitis. The hæmorrhage was but trifling and but few ligatures were applied. The abdominal incision extended about an inch above the umbilicus. A glass drainage-tube was introduced at the lower angle of the wound, and the remainder of the incision was closed with silver sutures.

At the close of the operation shock was not great, pulse 134. Morphia was given, and the patient passed a somewhat comfortable night. No vomiting. Morning of 19th, pulse 138, res. 34, temp. 100° F. Evening, pulse 140, resp. 30, temp. 102° F. Vomiting a little, and abdomen somewhat distended. Face pale and features pinched. Three ounces of pinkish serum from tube. Vomiting checked by swallows of hot water and a mixture containing creosote and sodii bicarb. Tube washed out with carbolized water. The third night was restless, with vomiting. Next morning, pulse 150, resp. 26, temp. $101\frac{3}{4}$°, increased stimulants, and at noon pulse was 138, resp. 26, temp. $100\frac{3}{5}$°. Fourth night, slept some, less vomiting, she takes koumiss, and retains it. Next morning pulse 140, resp. 20, temp. $100\frac{4}{10}$°. Fifth night, pulse 120, resp. 22, temp. $101\frac{4}{5}$°, stronger. Three ounces of a somewhat offensive fluid were taken from the tube, bowels were moved instantaneously. Sixth night she slept well, pulse 114, resp. 23, temp. $101\frac{1}{3}$°, sutures removed, union complete. Tube slipped out, and could not be introduced again. It left a canal, with healthy granulating walls. Seventh night vomiting returned. She did not receive the usual amount of stimulants during the night. Exhaustion and vomiting increased, without additional rise of temperature, and patient died on the ninth day. The death was doubtless due to exhaustion. The disease of the ovaries and of the peritoneum was doubtless colloid cancer. The tumors and the material removed from the peritoneal cavity weighed fifty pounds. It seems right to conclude that had the tumors been removed in their earlier stages, the patient would have, most probably, recovered from the operation, and have remained exempt from the disease months or years, or perhaps permanently.

Dr. Montgomery spoke of the advantages of early operation, before peritoneal involvement. He also alluded to the dangers of tapping. He gave a short history of a case of ovariotomy with colloid contents, and recovery from the operation, but followed by death six weeks later from cellulitis and ascitis, the cause being unknown.

Dr. Baer related a somewhat similar case, in which the patient recovered, but is now apparently dying from a recurrence of the disease in the upper part of the abdomen.

Dr. Parish, in closing, said that the tapping was done with reluctance, but did no harm in this case. The peritoneal complication made the case hopeless.

OFFICERS FOR 1885.

President—B. F. Baer, M. D.

Vice Presidents.—E. E. Montgomery, M. D., W. H. Parish, M. D.

Secretary—W. H. H. Githens, M. D.

Treasurer.—Alfred Whelen, M. D.

Librarian and Curator.—T. Hewson Bradford, M. D.

Council—Wm. Goodell, M. D., R. P. Harris, M. D., T. M. Drysdale, M. D., L. D. Harlow, M. D.

Publication Committee—J. H. Packard, M. D., B. F. Baer, M. D., J. C. DaCosta, M. D., J. B. Walker, M. D.

Library Committee—Horace Williams, M. D., D. Murray Cheston, M. D.

CHICAGO MEDICAL SOCIETY

Stated meeting, January 19, 1885.

Remarks on the Bacillus of Syphilis.—This subject was discussed at considerable length by Dr. Zeisler

The first half-dozen pages of his paper consisted of a translation from Dr Sigmund Lustgarten's communication on the "Specific Bacilli of Syphilis," delivered at the meeting of the Vienna Medical Society, November 21st last And as the subject is a very important one, a few extracts from the translation are herewith presented Dr Lustgarten "has succeeded in showing in microscopical sections from two syphilitic chancres and one syphiloma, bacilli which are perfectly characterized by their color reaction—by their form and relative position They are represented as straight or somewhat curved little rods, slightly larger, but having the same appearance as the bacilli of tuberculosis They are found singly or in small groups, enclosed in lymphoid, somewhat distended cells, and show under a powerful microscope light spots similar to those which Koch regards as spores in the tubercle bacilli The method of coloring makes it possible to distinguish them from the bacilli of lepra and tuberculosis, and from all other pathogenic bacteria as yet known The fact of their always being enclosed in cells excludes the possibility of deception by putrid formations," etc As a comparative illustration that the bacillus of syphilis is no rash conjecture, the writer alluded to the mistakes of Finkler and Prior, in Bonn, of stating the identity they claimed of the bacilli of cholera nostra and cholera Asiatica Likewise that Lostoffer, in Vienna, about fifteen years ago, thought he had found characteristic micro organisms in the blood of syphilitic individuals which he called corpuscles of syphilis, but which afterwards were found in lupus, and even in persons in normal health, and, furthermore, that as the author quoted from has made the culture of this bacillus, which has also been confirmed by Koch, it seems that such evidence is sufficient and should banish any doubt as to the importance of the new discovery and that it perhaps exceeds the discovery of the cholera bacillus, as syphilis is a disease of such general occurrence and not of epidemic character

Treatment of Syphilis with Hydrargyrum Tannicum —Nearly one year ago the first trials with this new remedy were made in the treatment of this disease, at Professor Kaposi's clinic in Vienna The results it accomplished were remarkable, and the advantages in using it were so desirable that it is now quite freely used in Germany by Gorges, Auspitz and others Mercury in any form is capable of producing specific effects in this disease, yet the method of introducing it into the system by inunction, or absorption, according to the writer, is not unscientific or invaluable So, too, is the method of subcutaneous injection of mercurial solutions, yet there are such disadvantages in using them in this manner as to utterly preclude it being done, as there may be, on the other hand, many cases where internal treatment, "per orem," is not practicable When the latter method is made use of, the protoioduretum hydrargyrum is mostly prescribed

Rapid absorption into the circulation without producing disagreeable effects is accomplished when the hydrargyrum tannicum is administered This remedy is a tannate of the protoxide of mercury It is without odor or taste, and is only soluble when decomposed The preparation contains about 50 % of metallic mercury Hydrochloric acid makes no sensible impression upon it If nitric acid is added, the remedy is easily dissolved Very dilute alkalis, ammonia, solutions of caustic potash, and the alkaline carbonates reduce it in a short time to a sort of magnesia composed of very small particles of metallic mercury The rapid absorption of this remedy into the system is proven by an abundant mercurial precipitate found in the urine shortly after administering it

The remedy is given in nearly all forms of syphilis—in recent eruptions, in moderate papular, pustular and gummous syphilides Twelve cases thus treated were then alluded to by the writer as having been published recently in a Vienna journal as cured, all of whom he had seen, and confirmed the report, and the surprising results obtained Six of the cases were primary eruptions, three cases were gummata, two were syphilides with small papules and large pustules, another was a relapse of secondary syphilis In from seven to fourteen days after the remedy was begun a rapid diminution of the lesions will be observed, and in three or four weeks they will have entirely disappeared In a case the writer treated recently, that of H G, æt 25, who contracted a chancre last June, and treated by another physician, when six weeks later roseola appeared, and with other various symptoms he had been taking a number of external and internal remedies up to Sept 14 About three months after the initial symptoms of the disease were manifested, Dr Z was consulted The patient at this date had a largely diffused maculo-papular syphilide Mercurial frictions were advised at once, until Sept 19, before the hyd tannate could be procured From this date until Oct 5 the patient took three decigrammes (equal to 4½ grains) of the preparation daily, at which time the eruption had entirely disappeared, and only a few pigment spots could be seen, nor was there any symptom of salivation observed The remedy was continued until the first of November, when the patient was discharged cured

The drug is usually given in doses of one decigramme (about 1½ grains), with four or five grains of sugar, three times a day, one hour after meals When it is thus given, it is rare that any symptom of mercurial salivation is produced Alkaline carbonates, considerable quantities of mineral water containing such salts should be avoided at the time the remedy is being taken, for these articles decompose the salt Neither must the administration of iodide of potassium be permitted, for the same reason, and besides, it would form a large amount of iodide of hydrargyrum

The writer has never seen any of the disagreeable symptoms of mercurial intoxication—stomatitis, salivation, etc , produced while a patient was using this remedy, as is often the case where other preparations of mercury are used , nor was there any irritation to the bowels induced where the remedy was taken for weeks in seemingly such large doses as four decigrammes, or about six grains, daily He had seen in all about twenty cases thus treated During the administration of it digestion remains good, and the bowels soluble, which is doubtless explained by the partial decomposition of the salt in the intestinal juices, and partly from the presence of tannic acid Should the bowels become loose, opium in one half centigramme quantities (one-sixth of a grain) could, if necessary, be added to each dose While this new remedy may not produce a revolution in the treatment of syphilis, the use of it deserves to be classed in the *role* of the best remedies likewise employed in the treatment of this disease

"*A New Method of Counting a Rapid Pulse*," is the title of a short paper by Dr A E Hoadley He admitted it was quite probable that it may have been practiced by others, or possibly described in some medical journal, but he had never seen it published, nor heard of any physician trying it Therefore he claimed it as original and worthy of record Before proceeding to a description of the writer's plan, it may be well to state his attention was attracted in this direction by reading an article, some months ago, on the same subject, in which the method referred to consisted in tallying the pulse with a pencil on a piece of paper for a fraction of a minute, and then counting the tally marks After making several trials of that method, which oftentimes is impracticable, he concluded that there must be an easier and more convenient way of counting a rapid pulse, which could be accomplished with greater facility, and be of scientific value His method consists simply in counting every alternate pulsation for a minute, and then multiplying the number by two In counting every other heart beat, one counts half as fas as the pulse is going, which with a rapid running pulse is deliberate A physician essaying this plan of counting a rapid pulse the first time, will in all probability fail in his attempt at making an accurate count, but with a little practice on a slower pulse, will very soon acquire the knack of doing so, and be enabled to count every other beat with positive certainty The plan proposed further consists in likening the pulse to the tick of a watch, and imagine a two and fro beat, and as soon as the mind is thus fixed, which will be almost instantaneously, then proceed to count the to or the fro beat, as the case may be, with perfect ease and certainty By placing the watch to the ear, one can demonstrate how easy it is to count every other stroke of the lever, while it is nearly impossible to count every tick of the watch In the plan suggested there is not a single objection, and in practicing it one can count a pulse twice as fast as by the usual way, and at the same time it has the advantage of being very easy and accurate

Obstruction of the Ilium caused by Peritoneal Adhesions—Death—Autopsy —A case of this kind was presented by the same gentleman who read the last paper All details of history and treatment are omitted as not being essential in this review, but a brief report of the symptoms, illustrating the manner of death, along with the pathology, as being sufficiently interesting, is herewith presented D P, a man 30 years of age, married, habits regular, had enjoyed apparent good health Was taken suddenly ill during the night of March 14 of last year with severe pain in the abdomen, opposite the umbilicus, which continued for five or six hours and then subsided, as was supposed, from the effect of remedies used But in spite of treatment, the pain recurred again after a few hours' interval, when it again abated These paroxysms of pain continued with greater or lesser exacerbations and frequency until his death, which occurred four weeks subsequently Soon after the attack he began vomiting, which was very distressing in its early stages, but this soon became passive, with but slight change each day until the final result was reached At times he vomited simply what was swallowed in the form of nourishment, while upon other occasions, especially during the first two weeks, the vomit consisted of stercoraceous matter For three weeks his temperature did not exceed 100° F, and most of the time it was nearly normal His pulse ranged between 75 and 85 per minute, which grew gradually weaker The last few days the heart's action was so weak and rapid that the pulse was scarcely perceptible at the wrist There was no tympanites, and but slight tenderness when pressure was made over the abdomen, which at times was quite flat and had a doughy feel When he suffered acute pain, the abdomen would become as hard as a contracting uterus in labor, although there was no muscular rigidity or increase of tenderness, and during the intervals, gently kneading the abdomen would induce the rigidity without provoking additional suffering Especially was this noticeable during the last days of the patient's illness, at which time he was much exhausted, his voice was husky, his skin lead colored, and he presented a generally pinched and emaciated appearance The pains also had lost their severe character, and instead, a sense of suffocation was produced, with diffused numbness, and, as he described his symptoms, he felt as though his stomach was being crowded up under his ribs Throughout his entire illness, with the exception of one day, there was not a voluntary passage from his bowels, although previously he had been regular in this respect By the aid of injections and laxatives this difficulty was in part overcome, in his having a successful passage every day or two of a few little elongated lumps of fecal matter, never exceeding three eighths of an inch in diameter At the end of the third week a slight diarrhœa set in for one day only Even in the absence of pain, he was restless and fatigued and slept but little, never to exceed an hour at a time Treatment was of little avail Opium and chloroform were the principal remedies used, they retarded vomiting and pain, but controlled neither Many other medicines were tried, and the case was treated from every possible standpoint of theory except surgical procedure, and there seemed to be no time when an operation would have been justifiable The utility of rectal alimentation gave evidence of beneficial results In consultation with Dr J D Skeer and Dr C W Earle, each of these gentlemen agreed as to the early diagnosis, namely mechanical obstruction of the small intestines, probably at the ileo cœcal junction, but of its exact character they opined not A favorable prognosis was not entertained, and he died on the twenty-eighth day

The autopsy revealed many peritoneal adhesions and bands of long standing, they were very firm, tying and binding the convolutions of the ileum down into the pelvic cavity One of these constricting bands was firmly attached to the anterior abdominal wall, half way between the umbilicus and the middle of Poupart's ligament on the right side At its attachment it was about one-fourth of an inch thick, and three-fourths of an inch wide It then spread downward to the left side of the pelvic cavity, where it was firmly adherent from the brim far down upon the inner wall, becoming fasciculated, and embracing the folds of the ileum between the fasciculi, furnishing a band that held the larger mass of the small intestines in the abdominal cavity It was necessary to divide these bands in several places on the pelvic wall before the intestines could be lifted out of the space they occupied, and when they were detached they were all tied together by bands of peritoneal adhesions, which did not present the slightest evidence of recent inflammation The bowel was inflamed, and very much softened for a distance of about four feet, which extended to within twelve or fourteen inches of the ileo cœcal junction There was no evidence of previously existing disease of the ileum It was uniform in thickness, although its caliber was contracted, the smallest place was about three eighths of an inch in diameter The intestines were so agglutinated at their sides, and bound down by cross bands, that peristaltic action must have ceased long ago Nature can accommodate herself to many unnatural conditions, but it is remarkable the functions of the bowels were performed so long and so well in this case Eight years ago the writer treated this patient for typhoid fever of a moderately severe form, which resulted in his recovery The most interesting point relating to the case, as it now appears, is, that at that time the patient had a moderate amount of peritonitis, which in all probability gave rise to the adhesions which subsequently and unquestionably caused death

STATE MEDICINE

MICHIGAN STATE BOARD OF HEALTH.

[Reported for the Journal of the American Medical Association]

At the quarterly meeting of the State Board of Health of Michigan, held January 13, 1885, at its office in Lansing, the following-named members were present Drs Avery, Lyster, Hazlewood, Tyler and Baker

The Secretary mentioned that during the quarter a successful sanitary convention had been held in East Saginaw, and that steps had been taken by citizens of Lansing to hold a sanitary convention in Lansing in March next (March 19 and 20, 1885) The Secretary had attended, as delegate of the Board, two meetings of Conferences of State Boards of Health—one in St Louis, Mo, in October, and one in Washington, D C, in December In the former he was chairman of the committee which prepared the report on practical means of preventing the introduction and spread of cholera in this country, which was adopted by the Conference, and also by the American Public Health Association It has been widely published In the Conference at Washington he read a report on the sanitary condition of Michigan and preparations made for meeting the threatened invasion by cholera, and was a member of the committee on best methods of action by the national government to prevent the introduction and spread of cholera

Bound volumes of the Annual Report for the year 1883 had been received from the printers, and this and other documents have been mailed to all health officers in the State, to clerks of cities and of villages, and to mayors of cities and presidents of villages A large number of circulars, in English and in foreign languages, on best means of restricting and preventing certain communicable diseases, had been sent to health officers where contagious diseases were present A large number of Annual Reports, reprints, and circulars have been sent to persons interested in sanitary affairs Blanks for reports of diseases dangerous to public health, with circular of instructions, were sent to all health officers of cities, villages and townships in the State, to the number of 1,390 Another set for reporting communicable diseases in 1884, was sent to the clerks of cities, villages and townships in Michigan. Two copies of a circular relative to diseases in Michigan in 1884, and stamped envelope for reply, have been sent to about one hundred and eighty physicians in Michigan who are regular correspondents of the Board

The Secretary also reported that, since October 7, there had been four outbreaks of cheese poisoning in Michigan—at Jackson, Homer, Flushing and Lansing During the past quarter there had been three cases of small pox, with one death, at South Boardman, Kaskaskia county, the infection of which is supposed to have been brought from Denver, Colorado

Many outbreaks of diphtheria had been reported during the quarter During the serious outbreak in Kalamazoo, from July 20 to December 20, 1884, over 260 cases and 54 deaths from diphtheria were reported to the Kalamazoo Board of Health The health officer of Kalamazoo reported, December 22, 1884, that the epidemic in that city appeared to be nearly or quite at an end, but since that report, *and following the thaw*, there was a sudden increase of diphtheria in Kalamazoo, 20 cases being reported in one week New cases of diphtheria continue to be reported from Detroit at the rate of about 35 to 45 per week The total number of cases in Detroit for the year 1884, as collated from the weekly reports of the health officer, is over 1,300, and the number of deaths for the same period is over 340

The secretary's reports of the Conferences of State Boards of Health held at St Louis in October, and at Washington in December, were ordered to be printed in the Annual Report for 1885

A letter from a gentleman in Bronson, in regard to sickness in his family, supposed to be due to arsenic in the wall paper of the house, was read by the secretary, and specimens of the paper were shown The paper was sent to Prof Vaughan, of Ann Arbor, to have it tested for arsenic

Dr Avery, as chairman of the special committee appointed at the request of the State Board of Corrections and Charities, to examine the State House of Correction at Ionia, read his report It was accepted, and ordered printed in the Annual Report for 1885, and copies were ordered sent to the committees on Public Health of the Legislature, and to the Board of Corrections and Charities The committee found the sewerage, plumbing and ventilation in bad condition The sewer leading from that part of the building where the offices are situated, empties into the basement instead of into the catch basin near the barn—that is, it empties at the wrong end There is no provision for flushing the sewer except by means of hose and hydrant The sewer has become filled up with garbage and refuse A new sewer should be laid, leading from the basement of the office building to the main sewer, for which there is ample fall The plumbing connecting the kitchen, wash-room, bath room and water-closets with this sewer is in wretched condition, and should be replaced with new, with properly ventilated soil-pipes and approved traps The committee consider the shafts designed to ventilate the cells as an admirable arrangement for the equal distribution of poisonous gases through all the cells, but can hardly call it ventilation In the shoe shops an attempt had been made to carry out the recommendations of a former committee of this Board, by placing steam coils in the few shafts put in when the shops were built, but the coils were not heated, and so were of no aid to ventilation No attempt to ventilate the other shops had ever been made In the cigar shop the odor of tobacco and foul air was simply intolerable, the committee noted the pallid faces of nearly all of the seventy-five or one hundred young men and boys in this room The water-closet of each shop has defective plumbing, and is unventilated, so that foul odors arising from them are permitted to enter the shops The ventilating flues leading from the hospital to the attic, are imperfect, and are not heated The committee recommended the prompt remedying of the evils by the employment of a competent architect to make plans and specifications, and to superintend the details of the work

Dr Jerome Walker's text-book, "Anatomy, Physiology and Hygiene," was approved by the Board according to law, for use in the schools of Michigan

The following-named text-books were conditionally approved under a resolution of the Board, passed July 8, 1884, which stated that, because of errors and omissions, until such errors should be corrected, the books named could not receive the entire approval of the Board

"Hooker's New Physiology, designed as a Text Book for Institutions of Learning By Worthington Hooker, M D Revised by J A Sewall, M D With a chapter on Alcohol and Narcotics 1884"

"A First Book in Physiology, for the Use of Schools An Introduction to the Larger Work by the same Author By Worthington Hooker, M D"

HEALTH IN MICHIGAN, JANUARY, 1885.

Reports to the State Board of Health, Lansing, by observers in different parts of the State, show the diseases which caused the most sickness in Michigan during the month of January (four weeks ending Jan 31), 1885, as follows

Number of weekly reports received, 171		*For preceding month*
Diseases arranged in order of greatest prevalance	*Per cent of reports stating presence of disease*	*Per cent of reports stating presence of disease*
Neuralgia	82	72
Rheumatism	75	77
Bronchitis	74	70
Tonsilitis	65	56
Consumption of lungs	61	54
Influenza	60	52
Fever, intermittent	50	53
Pneumonia	46	34
Erysipelas	37	25
Remittent fever	33	40
Diarrhœa	26	36
Inflammation of kidney	22	23
Whooping cough	18	17
Diphtheria	16	19
Inflammation of bowels	16	17
Scarlet fever	16	15
Membranous croup	14	10
Typho malarial fever	13	21
Typhoid fever (enteric)	11	16
Cerebro spinal meningitis	11	9
Inflammation of brain	9	5
Dysentery	6	6
Cholera morbus	5	6
Measles	4	4
Puerperal fever	4	5
Cholera infantum	2	3

For the month of January, 1885, compared with the preceding month, the reports indicate that pneumonia, erysipelas, neuralgia, tonsilitis, influenza and consumption of the lungs increased, and that diarrhœa, typho malarial fever and remittent fever decreased in prevalence

Compared with the average for the month of January in the seven years, 1879–1885, neuralgia and erysipelas were more prevalent, and pneumonia, diphtheria, intermittent fever, measles, dysentery, remittent fever and scarlet fever, were less prevalent in the month of January, 1885

For the month of January, 1885, compared with the average of corresponding months for the seven years, 1879–1885, the temperature was lower, the absolute humidity and the day and the night ozone were less, and the relative humidity was more

Including reports by regular observers and others, diphtheria was reported in Michigan in the month of January, 1885, at forty-two places, namely Attica, Boardman, Bloomingdale, Charlevoix, Chocolay tp, Dansville, Detroit, Delhi, Delhi tp, East Saginaw, Gaines, Gaines tp, Grand Rapids, Genoa, Harrisville, Handy, Hancock, Hastings, Hudson, Ingham tp , Imlay, Ishpeming, Kalamazoo, Lyons, Negaunee, Novi, Novi tp , Orleans, Oscoda, Oshteneo tp , Owosso, Pierson tp , Plymouth, Port Crescent, Quincy, South Boardman, Sand Beach, Thornville, Taylor tp , Watervleit, White Oak and Wyandotte, scarlet fever in thirty seven places Albion, Algonac, Bellaire, Belvidere tp , Clam Lake tp , Charlevoix, Detroit, East Saginaw, Faun River, Grand Rapids, Genesee, Highland, Homer, Ida, Kalamazoo, Leland tp , Lowell, Manistee, Muskegon, Negaunee, North Muskegon, North Lansing, Pontiac, Pierson, Pierson tp , Quincy, Sault Ste Marie, St Louis, South Haven, Sears, Sheridan, Thornville, Watervleit, Wheatfield, Whitehall and Westphalia, measles at four places Detroit, East Saginaw, Grand Rapids and Hopkins tp ,—and small pox at South Boardman HENRY B BAKER, *Secretary*

Lansing, February 5, 1885

FOREIGN CORRESPONDENCE

BERLIN LETTER.

BERLIN, GERMANY, Jan 10, 1885

MR EDITOR —The method of cultivating bacteria by the solid culture media, which is at present so largely occupying the attention of bacteriologists, particularly on the continent, is deserving of especial attention I feel the more liberty to say this now, and to explain the method a little in detail, because, like many others of my countrymen, I had a prejudice in favor of liquid cultures, especially when made in hermetically sealed bulbs, which I had used for several years previous to my coming to Germany I soon saw, however, that I had not fully understood the method of solid cultures, and that my objections, chiefly of the danger of the entrance of impurities, were more theoretical than practical, and that this method, on the other hand, does possess many special advantages,—for in no other way can a mixture of different forms of germs be so easily, quickly, and surely separated, and more especially, many forms of germs produce such peculiar appearances in their growth in solid cultures as to always distinguish them from all others

The materials most in use for solid culture media are gelatine (as "flesh-peptone-gelatine"), blood-serum, and aga-aga Probably most in use is the gelatine solution, which is prepared as follows

Half a pound (0 25 kilo) of fresh lean meat (beef or mutton) is finely chopped, and to it is added a pint (500 c c) of distilled water, the mixture remaining in a cool place for twelve to twenty-four hours It is then strained through fine linen gauze, the mass being pressed to extract all the liquid, which appears as a reddish-bloody fluid To this pint of "flesh-water" in a clean flask, is added 75 grains (5 grammes) of peptone, 30 grains (2 grammes) of common salt, and from 1 to 2 ounces (30 to 60 grammes) of fine gelatine, and to the flask is fitted a cotton-wool stopper The mixture should then stand for a half hour to allow the gelatine to swell up, and as gelatine has an acid reaction, enough sodic carbonate ($Na_2 CO_3$) should be added, to make the solution neutral or very slightly alkaline, because most germs do not grow in an acid solution The solution is then placed in a Koch's steam sterilizer and cooked for an hour This is an apparatus made of tin and covered with thick felt, by which the articles placed inside are exposed to the direct action of a large volume of steam

The solution is then filtered hot through filter-paper, and it comes through clear and yellow This is best done by means of a hot water filter, which keeps the gelatine thoroughly melted all the time If this, however, is not at hand, the ordinary glass filter tunnel and its contents may be warmed by carefully and quickly throwing against it the flame of a Bunsen-burner or a spirit lamp It should be emphasized that the filter and filter-paper, and the test-tubes, together with all the other apparatus used in the process, should be thoroughly sterilized in a sterilizing oven to a temperature of 300° F (150° C) for at least ten minutes

The next process is to fill the test-tubes, which have been fitted with a cotton wool stopper and sterilized as above described They are filled for about a quarter or a third of their length and are cooked for fifteen minutes in the steam sterilizer, when they are probably in a condition for use, but to make sure, it is better to cook them three days for fifteen minutes each day

Next week I will write you about vaccinating the cultures N

BERLIN, GERMANY, Jan 20, 1885

MR EDITOR —There are two ways of using the gelatine which has been prepared according to the method I described last week, viz plate cultures and tube cultures

(*a*) For plate cultures, which are especially useful to separate different forms of germs in a mixture, there is necessary an apparatus consisting of two bell-jars, a glass-plate, and glass bridges Of the bell-jars, which are about seven inches in diameter and two inches deep, one should be a trifle larger and a trifle less deep, to set over the other as a cover The glass plate should be about six inches long and four inches wide, but this should be regulated by the size of the table to one's microscope stand, for we must be able to examine every portion of it by the microscope The glass bridges should be such as to elevate the plate about one-quarter of an inch above the bottom of the bell-jar All of this, like everything, as I said before, should be sterilized in a sterilizing oven by exposure for ten or fifteen minutes to a temperature of about 300° F (150°C), and then it is put together to cool, the plate resting on the bridges in the lower bell-jar, which is covered by the larger one

When cold it is so placed that the plate is exactly horizontal, and for this purpose especial levelers are sold, which though convenient, are not absolutely necessary The cover being removed, gelatine melted in a test tube is poured over the plate so that when cold, there is a layer about an eighth of an inch thick The cover is replaced and all is set aside for the gelatime to harden when it is ready for vaccination, which may be done in two ways (a) Vaccination of the entire surface This is accomplished by making a *very dilute* mixture containing the several germs it is desired to separate, and pouring this over the surface of the gelatine (b) Vaccination in stripes This is accomplished by dipping a platinum wire sterilized by heat into the *very* dilute mixture of germs and gently scratching the surface of the gelatine This is repeated making the rows from a quarter to a half inch apart N B It is of great advantage to apply moistened filter paper to the inner surface of the cover to make a moist chamber Also, N B It is almost impossible to make too dilute a mixture, and beginners make a great mistake in this respect Theoretically it should be so weak that any one germ of a kind drops in a place and another at a little distance and so on This apparatus being kept at a temperature varying according to the cultivation, the plate shows, after twelve to forty eight hours, little points which grow and some of which may be distinguished from the rest By using these as seed in successive fractional cultures, the last becomes quite clean, when it may be transferred to a test tube culture

(*b*) The test tube culture is made in test tubes filled as above described, about one-third of their length and stopped by cotton wool

The vaccination is made by taking seed on a platinum wire sterilized by heat and thrusting it into the gelatine about an inch In their growth many germs build characteristic forms

Although no books give the information, it is to be noted that in making the vaccination, the test tube should be held inclined and with the *mouth* downwards when open, so that no outside germs may fall in from the air

For certain culture gelatine has the disadvantage of melting at a comparatively low degree, and when a higher one is necessary aga aga or blood serum is used

Aga aga is prepared like gelatine

Blood serum is prepared by filling sterilized test tubes one-third deep with clear serum from the blood of an ox or sheep, and cooking in the steam sterilizer at 135° F (58° C), for two or three hours During this time the test tube should be inclined at an angle of 45° to allow the serum to solidify in this position, which gives a much larger surface in the test tube for vaccination (N B Aga aga may also be thus prepared) The heating should be repeated for five days, when it is ready for vaccination with platinum wire

The solid cultures have many advantages, and I am glad if I have been able to clear it up to a few readers to whom it has been a mystery N

Berlin, Jan 20, 1885

The following interesting case came to Prof Frankel's clinic The man, some years ago, was affected with paralysis of the external rectus of the left side, which gradually disappeared under the use of iodide of potassium and mercury At present the patient has great difficulty in swallowing, and examination shows paralysis of the palato-glossus, palato-pharyngeus, tensor palati, crico-arytænoideus, post lower pharyngeal muscle, and paresis of the œsophagus on the left side Ten days' treatment with iodide of potassium has produced a marked improvement The character of the paralysis points to an affection within the cranium of the glosso-pharyngeal and pneumogastric nerves, and possibly of the accessorius on the left side

Placenta prævia was discussed by Dr Winter at the last meeting of the Obstetrical and Gynæcological Society At the same time Dr Schroeder demonstrated a frozen, complete longitudinal section of a woman at full term of pregnancy, with fœtus *in utero*, and the cervix just commencing to dilate This is the second section of the kind ever attempted, the first being made by Waldeyer The question of the proper treatment of placenta prævia is engaging very considerable attention, and from its discussion much good has resulted, both in regard to the mother and in regard to the child The first evidence of a more logical appreciation of the condition, of real, genuine, practical advance, was in the less frequent use of the tampon, which was a fecund source of infection, and which was merely tentative in *any* result—for it rarely worked for good, but generally for evil It has no effect upon the condition itself, and in its application much valuable time was lost If the placenta cannot be separated from its marginal attachments, or if it be a real placenta centralis, if the danger be imminent, the general verdict seems to be that we should turn by the bimanual method (Braxton Hicks), plunge through the placenta, draw down a leg, and tampon with it and with the breech of the child *Then wait for spontaneous delivery Do not extract at once, but wait* Hofmeier's and Behm's cases all confirm this view Just as soon as the cervix will permit the introduction of one or two fingers, rupture the membranes and turn With the whole hand in the vagina, this is as easily done by the bimanual method as it is with the whole hand in the uterus, and nothing is gained by waiting Naturally, there will be a strong hæmorrhage when the placenta centralis is ruptured—an alarming one, which might occasion fright, but this is immediately arrested by drawing down the leg I would like to urge this practice upon my professional friends in America The *tampon*, except in rare instances, is a nasty, dangerous appliance, and cannot possibly result in good I have seen much of this method of turning, and its results have been uniformly excellent

Dr Veit very kindly invited me to see some plastic work at his private hospital a few days ago He used the continuous stitch in a perineoplastic operation (mutton gut soaked in carbolic solution and hardened in alcohol) and painted the seam over with collodion At my suggestion, he used the same stitch and the same kind of gut in an operation upon the cervix (a so-called Emmet) I remembered that Dr Marcy, of Boston, had spoken to me of the feasibility of this plan in treating lacerations of the cervix, and I was very glad to have so early an opportunity of testing it It seems to me that it subserves an admirable purpose, it is less irritating and does away entirely with the subsequent necessity of removing the stitches, which one *must* do when silver-wire sutures have been used Dr Bergmann exhibited a man at his clinic from whom he had removed about four inches of intestine (colon) some time before The same day he opened the abdomen for the purpose of cutting out an extensive cancerous growth It was found to involve the spleen, the abdominal aorta, the intestine (duodenum and colon) and the stomach It was carefully dissected out, all vessels tied, the pyloric orifice of the stomach and about three inches of bowel were clamped and amputated The man was extremely anæmic when placed on the table, and during the operation, which lasted nearly three hours, every known device was made use of to keep him alive The operation was successful as a piece of surgical handiwork, but the patient did not live to enjoy it

It is said that Dr Lustgarten, of Vienna, while working in the laboratory of Prof Wiegand, at Leipsic, discovered a syphilitic *bacillus*, or *microbe*, which had the peculiarity of never being seen outside of its cell It is also said that Koch has verified these investigations Germany is crazed on the subject of bacteria Almost every one has a cultivating room, and the *fons et origo* of every known disease will probably, sooner or later, be represented by one of these little vibratory nothings If it be true that the bacillus of syphilis is never seen outside its cell, this may account for the development of symptoms in many cases The virus is deposited and remains harmless until some force shall free it from its imprisonment As scientific inquiries, these discoveries will always be of interest to the pathologist, but I cannot see that the contagium vivum theory and the known existence of bacilli, have done much for therapeutics

Prof Frerichs made extended experiments with the internal administration of germicides—carbolic acid, bichloride mercury, etc ,—in diseases of this kind, but without observing any good results But sound physiological therapeusis is advancing, every day adds something to its armamentarium, so that with a clear pathology we may hope for an equally clear plan of treatment I called the attention of Dr Martin to the recent addresses of Lausen Tait, "American Notes," in which he comments with some severity upon Listerism in general, and upon the German fashion of using the mercuric bichloride in particular I hope soon to give Dr Martin's views upon this matter Since he began strict antiseptic detail, out of 130 ovariotomies, he has lost only *one* from sepsis, and out of 66 laparotomies for myoma, his mortality has been 10 per cent His private hospital (thirty beds), probably the largest and best-equipped in Europe, is built upon the most approved antiseptic plans His room for plastic operations is entirely distinct from his room for laparotomies And not a single appliance that is used in the one is allowed to be used in the other No basins are used in the room devoted to abdominal surgery, and all the water used there is previously boiled I told Dr Martin that I believed that some cases recorded as "death from shock," might, with reason, be stated to be "death from a reduction of temperature," and that I was astonished to see so little provision made to keep the bodily temperature up He said that he did not believe that this had anything to do with the fatal results The only thing necessary was to ward off sepsis I hardly think this opinion will find general acceptance I believe it to be a most important thing to prevent a sudden lowering of temperature It may or may not influence the result to allow the contents of cystic degenerations to pour over the person of the patient, but it is certainly *neater* to use the *trocar*, and, so far as my investigations show, a safer plan as well

As a rule, American students of gynæcology in Berlin spend so little time here that they cannot watch cases and follow results They are, consequently, unable to express any decided or correct opinion of the value of the work done This can only be accomplished by remaining six months—or, better, a year—in one of the hospitals, and by familiarizing one's self with all the details of out-door and in-door service H R B

DOMESTIC CORRESPONDENCE.

HAMMOND, WIS , February 6, 1885

EDITOR JOURNAL AMERICAN MEDICAL ASSOCIATION .

Dear Sir—In a case of labor occurring in my practice, Saturday, January 31, 1885, the following facts seem sufficiently interesting for record 1st The age of the patient being 44 years, October 17, 1884, this was her first pregnancy, delivery by forceps, slight perineal rupture, patient doing finely so far She is a Norwegian, and here is the second interesting fact Her first husband, with whom she lived nearly twenty years, died some two and a half years since He was a leper, and the first and only case of leprosy I ever saw, and, so far as I am aware, the second case ever known in the State, the first authenticated case being under care of Dr Samuel C Johnson, of Hudson, Wis , now a member of the State Board of Health There *may have been other cases*, but these two are all I have any knowledge of, notwithstanding I am living in the very center of what the newspapers called, only a few months since, the " Leprosy infected district of the Northwest "

E L BOOTHBY

HUMANIZED OR BOVINE VIRUS IN VACCINATION.

EDITOR JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

I have been much interested in reading the report of the German Commission appointed to investigate this important question Careful clinical observation satisfied me years since that humanized virus has equal, if not greater protective power than bovine virus, that it is attended with less severe constitutional disturbance, and produces fewer ugly pustules, regardless of the agency whence the bovine virus came

The syphilitic scare has no terrors for me, although a London enthusiast appears to have settled affirmatively the question of its possibility With ordinary care it is practically impossible to convey such taint by means of vaccine lymph , while with extraordinary caution in securing healthy virus the danger of conveying any disease other than the one for which you vaccinate, has, in my judgment, no foundation in fact

It is true that latent impurity in the system may become manifest by vaccine fever So far, however, as my experience has enabled me to determine, bovine lymph is more productive of such development than humanized lymph—certainly not an argument in its favor Compulsory vaccination is becoming a recognized duty This being true, choice of virus should be optional with the vaccinated To determine satisfactorily the comparative value of humanized or bovine virus may require time and care That a great nation like Germany has considered it of sufficient importance to appoint a commission of learned men to investigate this matter, speaks much for the interest the nation takes in the welfare of her people and should stimulate to similar investigation in our own country

BOOK REVIEWS

A Text Book of Hygiene By George H Rohe, M D Cloth, 324 pages Baltimore Thomas & Evans

This book is a valuable compilation of the most important matters relating to the subject of hygiene It is comprehensive in scope, well condensed, clear in style, and abundantly supplied with references A work of this sort is necessary and will undoubtedly be improved by future editions In the consideration of the matter of ventilation the author is somewhat at fault He assumes the general principle that foul air rises, and recommends rules for ventilation accordingly The fact is, that in artificially heated buildings of all classes, public as well as private, the middle layer of air is that containing the least impurity and the best adapted as to temperature and humidity to the use of the inhabitants Impurities that rise can not be dangerous, as they occupy an inaccessible part of the room, while the denser impurities and cold air resulting from the loss of heat by connection as well as the leakage from without through the joints of the building, settle to the bottom This is the stratum that should be removed by ventilation through shafts, provided, if necessary, with heating apparatus to produce an upward draught Farther, the common plan of heating with small volumes of super-heated air, thus constantly diluting the atmosphere of the apartment with a thin stream of dry, hot air, often contaminated with the products of combustion, is one that should be condemned The hot air supplied should be in large volume and only sufficiently above the desired temperature to rise readily, and so by displacement remove the vitiated air of the room which should find a ready egress through the ventilating shafts, opening as before indicated at the lower part of the room

In the consideration of the subject of sewerage the author presents much valuable matter He particularly condemns the privy vault and recommends earth closets or the pail system in cases where a water carriage system is impracticable He is a strong advocate of the separate system, but as the combined, *i e* , that in which house drainage and surface water are both carried in the same pipes, which must be of large size, is the one now in general use, it is best to consider the means that may be employed for diminishing its evils to the minimum

The essentials of a combined system of sewerage are these First, a *complete* removal by gravity of all solids and liquids to a place of *safety* The proper place is a point below the level of the town, sufficiently remote from it and so arranged as to prevent an accumulation of the filth Second, the *complete* removal by ventilation of the sewer and all its branches, of all noxious gases to a place of *safety* The proper place is above the tops of the houses where the gases can be carried away by the wind or sufficiently diluted with pure air before being breathed by the inhabitants

These rules are constantly violated The practical plan of most sewer builders is to get the filth out of sight and to allow the gases to take care of themselves

In this digression we have quite forgotten Dr Rohe's book We have read it through, feel well repayed for the trouble, and justified in recommending it to the general and professional reader

Comparative Physiology and Psychology By S V Clevenger, M D , late Pathologist County Insane Asylum, Chicago , Member of the American Neurological Association, American Microscopical Society, American Electrical Society, American Association for the Advancement of Science, Chicago Medical Society, ex Meteorologist U S , Signal Service, Collaborator of the American Journal of Neurology and Psychiatry , American Journal of Nervous and Mental Disease, and American Naturalist

This new work includes eleven years labor in the fields its title indicates, and contains much original matter The intention of the author, we judge, is to elaborate a mental science to accord with recent physiological and anatomical research, which has been well done by him The reasoning is profound and appeals directly to experience As the author stated in his introductory remarks, the method proposed to examine the mind is an extension of Herbert Spencer's principles, and we believe is in accordance with the views of the majority of modern scientists We are pleased to notice a number of chemical formulæ in the manner in which they are arranged, as for instance, substituting CO which appears on the ninth line from the top of page 10, to denote carbonic dioxide So, too, regarding H_2O for sulphur, as it appears in the fourth line from the top of page 48 A number of similar illustrations might be cited

We trust the editor will appreciate a kindly suggestion of correcting a number of misspelled words, pertaining to what would appear possibly as being tautological in oft repeating the word rhythmical, as is found in the fifteenth line from the top of page 17, also rhythmic, in the twentieth line of this page, and again in the fourth line from top of page 31, as well as in a number of succeeding pages, and rhythm as found from the third line of the bottom of page 34 These may be typographical errors, however, simple in themselves, which is frequently the case in the first edition of any work, yet easily corrected by the reader But Dr Clevenger's reputation as a scientist will be satisfactory guarantee of the value of the book containing 257 pages, and we therefore commend it most cordially to our readers The printer and publisher have done their part of the work in good style It is also fully illustrated, the well known house of Jansen, McClurg & Co , of Chicago, being the publishers *Price $2 00* L H M

A Manual of Bandaging , Adapted for Self Instruction By C Henri Leonard, a m , m d , Professor of Diseases of Women, etc , Michigan College of Medicine Second Edition Detroit Pp 159 Price, $1 50

This is a useless little volume since it contains much discarded rubbish of obsolete names and the terminology of a past generation It is full of references to "charpie" the "plumasseau," "Gateau," "boulette," "bourdounet," "pelote," "cataplasma carbonis," and other strange and barbaric things which modern surgery has no use for It is evident enough where the writer's mistake occurred In compiling his "manual" he used one or two little works on bandaging which are still extant upon the shelves of older practitioners The book has every appearance of having been made to order by one who knew little or nothing about the subject A little more practical experience would have taught him that more than half his elaborate bandages with their queer long names would not work in practice, in fact have been discarded long ago, if they ever were in use It may be that they are still popular in Detroit, but not in the rest of the world How singular that such a book should be printed, when we have had for several years the excellent works of Gamgee and so many others on bandaging and dressing of wounds and fractures! Since it is nothing but a compilation, why not have compiled something from an enlightened source? The preface informs us that the work has been used in medical colleges, but there must be some mistake about this The student who should make this manual his authority would be a veritable Rip Van Winkle when he emerged from college It is also well known that in the United States *all* medical professors are men of thorough education and high standing, who could not make the mistake of supposing that this book would be of any use to the present generation

Surgical Handicraft A Manual of Surgical Manipulations, Minor Surgery and other Matters Connected with the Work of House Surgeons and Surgical Dressers By Walter Pye, f r c s Philadelphia P Blakiston Son & Co Cloth, 544 pp , 208 woodcuts Price, $5

This volume will be of value as a book of reference It treats of a numberless variety of matters coming within the province of the hospital house surgeon and general practitioner Every man has his own methods and those are best in his hands with which he is most familiar, still suggestions are always useful and amendments always in order Each reader will probably wish to make some alteration in the book, for it treats of those matters of which every one has practical knowledge Your reviewer, for instance, would like to suggest that in his experience the incorporation of metallic strips into plaster splints does not add permanent strength to the splint, for it divides it up into layers which make the splint break down quicker than a simple one made of selected plaster The important point in this connection which is omitted by the author, as well as practically ignored by most surgeons, is that the plaster used should be of the best Old plaster that has been for months in a drug store and has absorbed a large quantity of atmospheric moisture, not only sets slowly but makes a weak, crumbling splint inferior to one from the freshly prepared article Heating in an oven *does not* entirely restore the quality of old plaster

The book is supplied with marginal notes and portions of it might be conveniently used as a text book for medical students in minor surgery, while the entire work is worthy of a place in any library

Handbook of Ophthalmic Science and Practice By Henry E Juler, f r c s , Junior Ophthalmic Surgeon to St Mary's Hospital Senior Assistant Surgeon and Pathologist to the Royal Westminster Ophthalmic Hospital, Moorfields, *with one hundred and twenty-five illustrations* Published by Henry C Lea's Son & Co For sale by Jansen, McClurg & Co Price, in leather, $5 50

Although there are some excellent additions by Dr Chas A Oliver, the American editor, yet taken as a whole it is in no wise superior to many others already in the field, and in some respects much inferior There is a great number of illustrations—one hundred and twenty five—many of which are wholly uncalled for, and occupy space that could very well have been better utilized What advantage to figure an entire set of Bowman's probes, a lachrymal syringe or a lid retractor?

The chromo-lithographic plates are, artistically considered, beautifully executed, yet those relating to diseases of the cornea and lens would puzzle more than aid a student in forming a diagnosis

On some subjects the author has not kept up with ophthalmic progress No reference is made to Hotz's operation for entropion (Knapp's Archives Ophth , vol 8, p 249) which is far superior to any previously devised Dewecher's method of using jequirity is very briefly given and the author's observation (p 95) that "it does not affect the cornea injuriously" is wholly wrong and apt to lead to injurious consequences Treatment of detachment of the retina is far from being up to date Errors of refractions are fully considered and Dr Oliver gives a description of a new astigmatic disk with an explanation of its use

The mechanical portion is all first-class, as one would expect coming from the house it does, excellent quality of paper and good type L W

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS By FRANK HASTINGS HAMILTON, A B, A M, M D, LL D, late Professor of Surgery, Bellevue Hospital College, etc, etc Seventh American edition Philadelphia H C Lea's, Sons & Co 1884

The seventh edition of this standard work is larger and better than any which have preceded it In his latest preface Professor Hamilton claims to have embodied in the new edition all the recent contributions to this wide subject which has now quite an extensive literature, but which was so little written about once that the first edition (1859) declared, "The English language does not at this moment contain a single complete treatise on fractures and dislocations"

Although it is literally true, perhaps, that there was no existing work on both fractures and dislocations, it would be a mistake to suppose that Professor Hamilton's book was a pioneer in this field, for Sir Astley Cooper's classic work on the dislocations must claim that position

That exhaustive work has furnished the basis of all subsequent surgical literature on the same topic, including Hamilton's treatise

A very large number of the engravings are direct copies of those in Cooper, of course, and yet neither this nor any modern treatise has ever reproduced them in a style equal to the originals

Considerable changes have been made in this edition The work of Dr Lewis A Stinson on fractures is one which the author acknowledges to have found of service He also makes especial mention of the original investigations of Dr A Poinsot, of Bordeaux He declares, however, that he attaches less importance than many to the experiments upon the cadaver to determine the mechanism of dislocations and fractures near joints

The value of these experiments is freely acknowledged, and yet with a certain reserve which is half ungenerous This great work, in its latest issue, will command more than ever a position of undisputed authority as the best treatise in any language in the field which it attempts to cover E W A

NOTES ON THE OPIUM HABIT By ASA P MAYLERT, M D Third Edition, Revised and Enlarged New York G P Putnam's Sons, paper, 47 pages

The fundamental cause of the opium habit, aside from the accidents which may arouse it into potent energy, is in the moral nature of the individual Dr Maylert does not take quite as broad a view of the subject as that above suggested, but recognizing the psychical element in the cause eloquently insists on the use of moral measures in the case In fact he recommends that therapeutic agents should be employed to meet the various symptoms that may arise, while the entire confidence of the patient and the gradual diminution of the dose are the prime requisites to success He also considers that the patient should be kept under surveillance for a considerable length of time after the opium is stopped or until the normal degree of self control is reached He is greatly opposed to the sudden entire stopping of the drug as subjecting the patient to dangerous and unnecessary suffering There are, however, well authenticated cases where the drug has been entirely stopped, and an inert substitute, which the patient supposed to be opium, had answered every purpose in allaying the distressing symptoms The success of this stratagem is hardly to be expected in those cases when the protracted use of the drug has produced marked *nutritive* changes in the patient

MISCELLANEOUS

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY, FROM JANUARY 31, 1885, TO FEBRUARY 6, 1885

Waters, Wm E, Major and Surgeon, granted leave of absence for one month (S O 24 Department of the East, Jan 31, 1885)

Taylor, B D, Captain and Assistant Surgeon, granted leave of absence for one month, to take effect between March 15 and April 1, permission to leave Department limits (S O 10, Department of Texas, Jan 26, 1885)

OFFICIAL LIST OF APPOINTMENTS, PROMOTIONS AND CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, JANUARY 1 TO 31, 1885

Stoner, G W, Surgeon, When relieved to proceed to Washington, D C, for duty as chief of Purveying Division Jan 16, 1885

Benson, J A, Passed Assistant Surgeon When relieved to proceed to Chicago, Ill, for duty Jan 12, 1885

Carmichael, D A, Passed Assistant Surgeon When relieved to proceed to Cairo, Ill, for duty Jan 3, 1885

Ames, R P M, Passed Assistant Surgeon When relieved to proceed to New York, N Y, for duty Jan 14, 1885

Urquhart, F M, Passed Assistant Surgeon To proceed to Norfolk, Va, and assume charge Jan 12, 1885

Brooks, S D, Assistant Surgeon To proceed to Evansville, Ind, and assume charge Jan 14, 1885

Carrington, P M, Assistant Surgeon To report to Surgeon in Charge, St Louis, Mo, for temporary duty Jan 17, 1885

PROMOTION

Stoner, G W, Surgeon Promoted and appointed Surgeon by the Secretary of the Treasury, from January 16, 1885 Jan 14, 1885

APPOINTMENT

Carrington, Paul M, M D, of Georgia, having passed the examination required by the Regulations, was appointed an Assistant Surgeon, by the Secretary of the Treasury, Jan 16, 1885

FOSSIL TRUSSES

A CLINICAL LECTURE BY E ANDREWS, M D , SENIOR SURGEON OF MERCY HOSPITAL

In every hospital there is apt to be some dark closet which becomes by degrees a sort of museum of rejected apparatus It slowly grows to a small mountain of old instrumental fossils, full of all sorts of broken and discarded trusses, aborted splints, deceased galvanic batteries whose dry cells no longer throb, and patent wooden legs, whose inventors died in poverty, because the legs would not run under the patients, nor the patients run after the legs

My learned friend, Prof D R Y Cobwebs, has been excavating with great enthusiasm in our mountain He declares that these fossils are arranged in regular decennial strata, with the ideas expanded horizontally, and that by the aid of his wonderful new science of comparative instrumentology he can tell the age of every specimen, from the primeval implements of Brainard up to the quaternary appliances of Andrews, Hollister, and Dudley He goes still further and maintains that there is evolution here that our mountain has been developed by a kind of unnatural selection and the survival of the unfittest, so that in its deposits he can find relics of the pet hobbies and cranky experiments of all the surgeons within a hundred miles of this place The great Cuvier from a few fragments of bone restored and pictured the entire form of the extinct Palæotherium It is true his picture proved afterwards to be entirely erroneous, but no matter for that, it was a very learned restoration, so our Prof Cobwebs claims that from a few pads of old fossil trusses, with here a screw and there a buckle, he can depict the progress of past surgical thought just as well as Cuvier did—or didn't—restore the Palæotherium

I can never hope to equal such all embracing learning, but nevertheless I may interest you by showing from his collection a few fossil trusses, and tracing the evolution from their crude forms down through various changes into the modern elegant styles The first man that had a hernia must have learned that he was free from distress only when he kept it reduced, and beyond doubt he resorted to some device to make pressure for that purpose In short, he made a truss The most ancient method which we know anything about was to put a tight belt of rawhide, leather, or cloth, around the hips, and attach to it a thick pad to press upon the hernial ring This primeval invention is still occasionally reproduced Here is a specimen brought in by an old prairie farmer It consists of a thick cowhide belt buckled about the hips, and having attached to it a very large pad stuffed with wool It did him some good in quiet walking, but always slipped to the wrong place under active exertion Besides, the pad is too wide and merely fumbled about the opening without pressing firmly at any one spot The farmer got it up himself by the aid of the village saddler, and it represents, I suppose, the ancient primeval truss of man's first efforts

Here is another specimen, which was excavated from stratum No 2 It is a double truss The ingenious inventor, who was probably a tailor, first made a strong linen belt to buckle around his hips, and attached two pads, one to press on each inguinal ring He seems to have found this, like the farmer's cowhide belt, to be prone to slip upward He therefore sewed on a couple of perineal bands to hold it down This was effectual in one direction, but then it sometimes slipped downward He next sewed on a long pair of suspenders, to pass over the shoulders and hold the belt up Thus was evolved the complicated harness which you here see

Here is another fossil When the art of weaving elastic fabrics containing rubber threads was invented, the inventor of this specimen made a broad belt of the new fabric, and prepared a peculiar elastic pad to attach to it This truss was extensively advertised in the West twenty-five years ago It served a tolerable purpose on many patients, but is now as extinct as the Megatherium The difficulty with all belt trusses for inguinal hernias, is the impossibility of making them hold their position during the varied movements of the body, and the difficulty of making the pad press in firmly at a position where the belt draws nearly straight across the body Woodward, of the United States Army, and other writers strongly condemn them, but still they hold their ground for umbilical hernias, and in that situation they do very well About a hundred years ago an improvement was attempted, by making a steel hoop to lock around the hips and to hold the pad firmly in place Here is an ancient fossil of this sort, which has come down to our times by the power of Prof Cobweb's great principle of the survival of the unfittest This particular specimen was evolved by the village blacksmith, after his brain had been fertilized by the vegetable energies of a neighboring root doctor It consists of a mighty steel cycloid, screwed to a wooden wheel to rest on the back, and carrying a copper pad in front, of the shape and size of a teacup The whole is wound with many layers of rags of most venerable antiquity

Early in the last century the modern plan of steel springs to clasp the body from one side was developed, and, so far as I can trace the history, it appeared first in Scotland The superior security with which this kind of truss held to its position in all movements of the body, soon enabled it to drive the belt trusses out of use A long series of doctors, quacks and cranks took out patents for endless modifications of this style, and some of the improvements were very good From lapse of time the patents have mostly expired, and now all the really important principles are freely used by every manufacturer, hence many varieties of good trusses are in existence

One of the earlier forms is still widely manufactured, and is worn with excellent results by thousands, and being both cheap and efficient it commands a wide sale It consists of a steel spring, bent as in this pattern, and carrying an ovate pad to press upon the inguinal or femoral ring Like all modern trusses of the sort it is applied around the side of the hip between the trochanter and the crest of the ilium, clasping the pad upon the required part Many of those sold here are hand-made by Degenhardt, who deems it important that the spring shall be hammered by hand and given a sort of curve on its axis It is hard tempered, because he claims that the softer tempers usually employed to enable one to modify the curve in fitting on, allow the spring to bend slowly out of shape as it is worn It is covered with leather and chamois skin Thus constructed, this style of truss generally fits well if properly selected, and is very cheap All leather covered trusses, however, lack durability, for the sweat rots the leather and rusts the spring, causing it to break after a few years and necessitating a new one This form is a favorite with the Germans To render them more durable some manufacturers make the pad of celluloid, and cover the spring with the same This gives greater durability, but increases the price materially Figures 1 and 2 give an idea of the general form

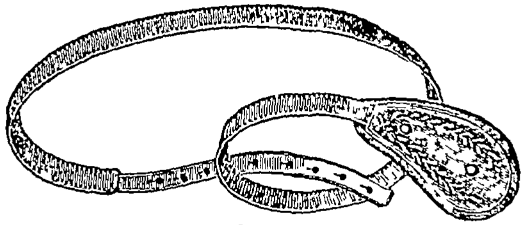

Fig 1

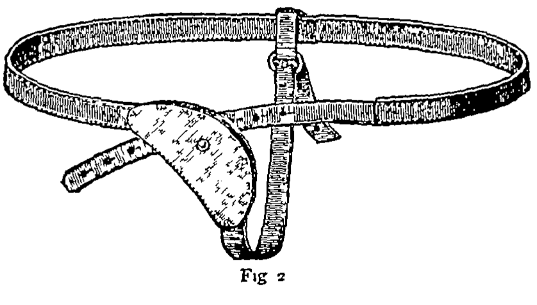

Fig 2

Many years ago a class of trusses sprang up, one of which was called the Hull truss (Fig 3)

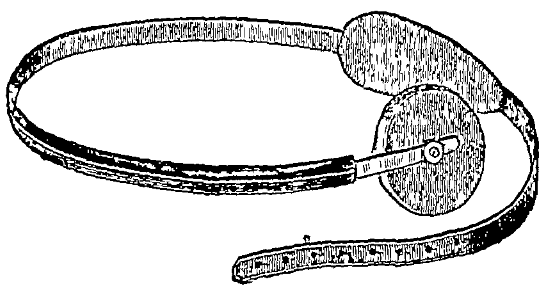

Fig 3

The spring was a segment of straight hoop of steel, not being given the composite curve, and the pad was too broad and flat, preventing the pressure from being concentrated at the desirable point It is gone to the land of fossils

Some twenty five years ago appeared the first hard-rubber truss, sold at the East under the name of Riggs' Truss, and at the West, named after one Seeley The spring had a single curve, like the preceding one, and was made long enough to reach across the middle line of the body and compress the side opposite the one clasped by the instrument The spring was composed of a band of steel, covered with polished hard rubber, and could be altered in form somewhat by heating the rubber and bending it outward or inward The pad was a marvel of foolish ingenuity It consisted of a cross of metal, each arm of which carried a little ball of hard rubber These four balls were applied around the inguinal ring, leaving the centre unsupported The astute inventor explained that these balls would draw the ring together and thus close it up The absurdity of the thing seems to have been too much for the truss to hold, for the manufacturers soon changed the form of the pad and substituted one of more ordinary shape Thus improved, the instrument did fairly good work in a great many cases, but did not fit as well as those shown in Figs 1 and 2, yet it had a considerable sale on account of its power to resist the effects of perspiration and of its consequent durability They are now nearly gone out of use, and must be classed with the fossil trusses The introduction of celluloid into the manufacture of trusses hastened the exit of the rubber instrument The pleasant pink color of the celluloid used makes it a favorite material, and as its use is not limited to any one form of truss, it can be had in various forms The springs and pads are made of steel, covered with celluloid, which protects the metal from perspiration and rust It has been charged that celluloid, being partly composed of gun cotton, will explode and blow to atoms any shop or store where they may happen to be set on fire This is an error Celluloid will not explode If I take this broken truss and touch the end of it to the flame, you see it merely burns freely, like a small torch, but shows no detonating qualities This class of instruments is sold in Chicago by E H Sargent & Co As the celluloid may be applied to almost any form of instrument, its use in the future will not constitute a particular species of truss, but rather a good method of covering various trusses, so as to exclude the perspiration and secure durability

A very excellent instrument is furnished by the United States government to ruptured soldiers It is made in Chicago by Dr A H Parker, under the trade name of the "Common Sense Truss," and extensively sold to patients (See Fig 4)

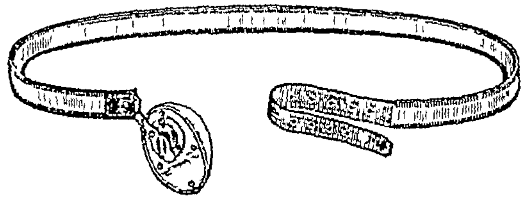

Fig 4

It consists of a steel spring, covered with a strong woven sheath, which is generally silk The sheath terminates in the usual leather strap to fasten in front The pad is of ivory or other smooth material and carried on a short arm, which can be set in different directions so as to fit the patient and change the instrument for use either with a right or a left hernia The pad is articulated with a ball and socket joint, fixed with a set-screw The temper of the steel admits of being bent to fit the form without breaking

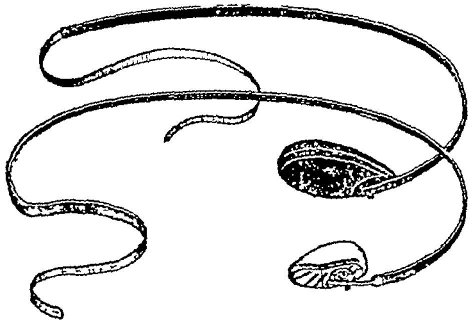

Fig 5

The length of the spring is somewhat greater than in most trusses as shown in Fig 5, where the upper one is of the common kind The increased length of the lower one fixes it more steadily on the hips It is a very excellent truss

Sharp & Smith sell largely a truss which pleases many patients It has a good steel spring like nearly all the trusses now in use, and the pad is attached to it by a revolving ratchet bar to enable the pad to be set in or out at pleasure The other end of the bar is secured to the pad by a screw and a dowel-pin, which permits of other changes of position (See *Fig 6*)

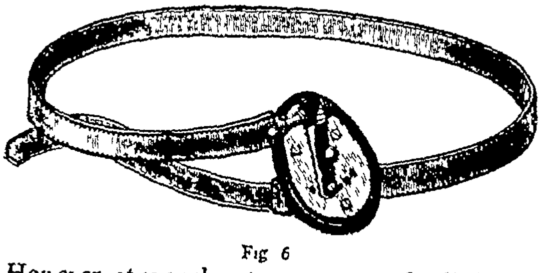

Fig 6

However, it is useless to try to specify all the good trusses in the market It will be more useful to you to sum up briefly the points to be attended to in fitting out a patient who has a common inguinal hernia It is best either to take him to an establishment where a large number of trusses can be tried, or else to carry a large assortment to his residence The principles involved in the fitting are these

1 The hernia must first be reduced No patient can bear an ordinary truss pressing upon the intestine

2 If the hernia is oblique, apply the truss squarely upon the internal ring, or a trifle downward and inward from that position

3 If the hernia be a "straight" one, or if it be a direct one, apply the pad upon the external ring, but do not put it upon the os pubis No patient will tolerate the instrument if it pinches the skin against the bone

4 When applied, have the patient test it by coughing, straining, running and jumping If it holds the gut, under these tests, and does not slip from its position nor hurt him, it will be for him a good truss, whether it fits anybody else or not The main point is to be comfortable to the patient, and to hold the gut These ends being secured, the numerous minor modern improvements are of secondary consequence

5 In fitting peculiar cases, the minor points come to the surface, and are briefly these A person who sweats copiously destroys woven and leather covers, and rusts steel springs rapidly Celluloid covers last such cases longer The pad should be proportioned to the size of the ring, not plunging into it like a plug, nor spreading all around it like a flat wheel Perineal bands are useful in some cases, especially in femoral hernias

Cup shaped pads are useful in some irreducible hernias, and suspensory bags in others Belt-trusses do well in umbilical hernias, but spring-trusses serve also, if the rupture be not large Springs, with a hard spring-temper, keep their shape best under long wear, but if they do not fit well, they cannot be altered A softer temper enables you to modify the shape of the spring to fit the peculiarities of the individual form, but if it be a little too soft, the spring will slowly yield and require to be frequently bent in again to maintain the pressure Leather or silk-covered pads are pleasing at first, and hold their positions well, but as they become soiled or rotted with sweat, they require repairs Wood, ivory, celluloid, and other hard substances last very much longer, but are more expensive at the outset

HISTORY OF A CASE OF NEPHRORAPHY, WITH REMARKS

BY L H DUNNING, M D , OF SOUTH BEND, IND

Mrs G H , aged 44 years, American , of large build and strong , previous to the present illness had been robust About seven years ago she lifted hard upon an iron kettle and felt something give away in wooden wheel to rest on the back, and carrying a copper pad in front, of the shape and size of a tea-cup The whole is wound with many layers of rags of most venerable antiquity

Early in the last century the modern plan of steel springs to clasp the body from one side was developed, and, so far as I can trace the history, it appeared first in Scotland The superior security with which this kind of truss held to its position in all movements of the body, soon enabled it to drive the belt trusses out of use A long series of doctors, quacks and cranks took out patents for endless modifications of this style, and some of the improvements were very good From lapse of time the patents have mostly expired, and now all the really important principles are freely used by every manufacturer, hence many varieties of good trusses are in existence

3 If the hernia be a "straight" one, or if it be a direct one, apply the pad upon the external ring, but do not put it upon the os pubis No patient will tolerate the instrument if it pinches the skin against the bone

4 When applied, have the patient test it by coughing, straining, running and jumping If it holds the gut, under these tests, and does not slip from its position nor hurt him, it will be for him a good truss, whether it fits anybody else or not The main point is to be comfortable to the patient, and to hold the gut These ends being secured, the numerous minor modern improvements are of secondary consequence

5 In fitting peculiar cases, the minor points come to the surface, and are briefly these A person who sweats copiously destroys woven and leather covers, and rusts steel springs rapidly Celluloid covers last such cases longer The pad should be proportioned to the size of the ring, not plunging into it like a plug, nor spreading all around it like a flat wheel Perineal bands are useful in some cases, especially in femoral hernias

Cup shaped pads are useful in some irreducible hernias, and suspensory bags in others Belt-trusses do well in umbilical hernias, but spring-trusses serve also, if the rupture be not large Springs, with a hard spring-temper, keep their shape best under long wear, but if they do not fit well, they cannot be altered A softer temper enables you to modify the shape of the spring to fit the peculiarities of the individual form, but if it be a little too soft, the spring will slowly yield and require to be frequently bent in again to maintain the pressure Leather or silk-covered pads are pleasing at first, and hold their positions well, but as they become soiled or rotted with sweat, they require repairs Wood, ivory, celluloid, and other hard substances last very much longer, but are more expensive at the outset

---

HISTORY OF A CASE OF NEPHRORAPHY, WITH REMARKS

BY L H DUNNING, M D, OF SOUTH BEND, IND

Mrs G H, aged 44 years, American, of large build and strong, previous to the present illness had been robust About seven years ago she lifted hard upon an iron kettle and felt something give away in the right side She was ill for some time after this strain, and attributed her illness to some injury done to an internal organ Commencing six years ago, she was for three years confined to the bed the greater part of the time Of the nature of her disease, at the commencement, I am unable to say, since she was seen by many physicians, no two of whom agreed in the diagnosis of her case Four and one-half years ago she came under my observation and treatment Then there were ascites and anasarca, and pain in the pelvic region The urine was slightly albuminous I thought her a subject of chronic Bright's disease, but soon changed my opinion, as the dropsy was readily relieved, and the albumen disappeared from the urine Later on in the case, I found a tumor in the posterior wall of the body of the uterus, and another in the hypochondriac region These we concluded, after consultation, to be fibroid tumors, which were treated upon the non-interference plan Three years ago she began to improve, left the bed, and commenced light hand work Last February (1884) she had a severe attack, the main symptom of which was an intense pain in hypochondriac and lumbar regions This pain was at first supposed to be due to neuralgia, from which she suffered much and often It resisted all forms of treatment for weeks At times it was agonizing, and could only be relieved by large doses of morphine or by chloroform inhalations After eight or nine weeks the patient was better, but she was greatly emaciated The fat had nearly all disappeared from the walls of the abdomen, and I was able to better examine the contents of the abdominal cavity I now concluded that the abdominal tumor before found, and now easily outlined, was a movable kidney, and that the intense pain she had suffered was due to a stretching or twisting of the nerve supplying the kidney The range of motion in this tumor was great It could be moved without undue force two inches to the right of the umbilicus and two or three inches below the same point From these localities a slight pushing movement would cause it to glide back to its place beneath the right lobe of the liver By pressing upon the eleventh and twelfth ribs (right side), the patient could shoot it across the abdomen to the left of the umbilicus The outline of the tumor could be felt and it was distinctly kidney-shaped During the summer several physicians saw the patient, and concurred in my diagnosis

I stated to the patient the possibility of fixing the organ by an operation She urged one, and I finally consented to undertake it

Oct 30, assisted by Drs Kettring, Kilmer and McAllister, of this city, I proceeded to operate, adopting the plan described by Dr Robt F Weir in a clinical lecture published in the New York *Medical Journal*, Feb 11, 1883

The operation consisted in cutting down upon the kidney in the lumbar region, and stitching the fat and capsule to the edges of the wound Our incision extended from the twelfth rib to the crest of the ileum, was parallel to the spinal column and two and one-half inches to the right We were able to readily bring the posterior surface of the kidney into the wound or to push it away from the wound several inches In this way were we able to confirm our diagnosis The posterior surface of the kidney was crowded firmly into the bottom of the wound, and the fat and capsule firmly united to the edges by catgut sutures

Four stitches were used along each border of the incision Three stitches I thought at the time passed through the renal capsule, and the remainder through the peri-renal adipose tissue A drainage tube was placed in the bottom of the wound and fastened there The wound was left open to heal by granulation The full antiseptic dressing was used, a compress placed upon the right side of the abdomen and the whole held in place by a wide bandage Full antiseptic precautions were employed, except the spray

The patient rested well, and at nine o'clock, ten hours after the operation, the temperature was 96¾ degrees, and the pulse 78 per minute She was looking bright and cheerful, and had taken some liquid nourishment with relish Two-thirds of a pint of urine was drawn with the catheter The temperature and pulse records in the case are uninteresting, and will not be given in detail The highest temperature reached was twenty hours after the operation, when it was 99 9, and the pulse seldom reached a higher rate than 80 per minute The second day the wound was dressed, and found in a healthful condition, but we found, to our surprise and disgust, the knots holding the sutures including the deeper portions of the investments of the kidney had pulled out, and one end of each had drawn into the tissues out of sight The remaining sutures were intact, and held the kidney firmly against the bottom of the wound During the dressing an assistant made firm pressure upon the abdomen, in the hypochondriac region, to prevent any displacement of the kidney, and this precaution was observed during each subsequent dressing All went on well with the patient and wound until recovery had taken place Not an untoward symptom arose, and at the end of six weeks the wound had entirely healed

During this time the compress had been held firmly in place by a bandage encircling the abdomen Now, upon the removal of the bandage with the patient lying upon the left side, it was found the kidney moved slightly away from the position in which it had been anchored, and we were made aware of the fact that our efforts had not been entirely successful

January 30, I examined the patient in respect to the effects of the operation, and learned that the kidney was movable to the extent of about one inch in a transverse direction, but not in any other direction

That the patient has been much relieved by the operation is apparent She is quite well satisfied with the results, though the relief was not so great as she anticipated I would not have trespassed so long upon the time of the reader of this detailed history, were it not that there are several points of interest connected with it that merit more than a passing notice

The number of operations performed for the fixation of a floating kidney are comparatively few since the operation is of recent origin, and the number of cases requiring operative proceedure are limited , hence it is that all points connected with the modus operandi are not as yet definitely settled One of these points relates to the investing parts of the kidney to be united by suture to the edges of the wound

In the first two cases operated upon by [1]Hahn he passed the sutures through the peri-renal fat, and in one of them the result was not entirely satisfactory, so in the third case he included a portion of the renal capsule in the suture [2]Gilmore records one case in which the suture cut its way out of the renal capsule and set the viscus free The author of the article in Ashurst's Surgery already quoted, states "Experience will have to decide whether there is any necessity of penetrating the envelope of the kidney " That the kidney can be more firmly fixed at the bottom of the incision if the sutures pass through, and include both the peri-renal adipose tissue, and renal capsule, I have no doubt, but I am convinced after a number of experiments made upon the kidney, and its investments soon after the slaughter of the animal (sheep) that if the peri renal fat and capsule are intact, *i e* , if they retain their intimate relations and attachments to the kidney, which may be ascertained when that organ is exposed by the incision, there is no need of attempting to include the nearer investing capsule of the kidney, for I found the attachments of the former to the latter strong enough so that if secured by a single suture it would bear the weight, without tearing, of more than two normal kidneys Apply now eight or ten sutures, at proper intervals, throughout the length of the posterior surface of the kidney, and I believe it will be so firmly held in position that deeper sutures will not be required Further, I found during the experiments just referred to, that unless the renal capsule is detached, and lifted up by drawing upon the peri renal adipose tissue, it is exceedingly difficult of separation from the organ which it envelopes I made several attempts with my dressing forceps to raise the renal capsule, but failed in every instance, unless sufficient force was exerted to wound the tissues of the cortical structure of the kidney With small tissue forceps I could do somewhat better, and with small conjunctival forceps, if care were used, the capsule could be readily seized, and quickly separated from the organ In this way, an area of capsule probably one inch in diameter, could be lifted up without tearing it or wounding the kidney The dressing forceps were of service in carrying forward the work begun by the more delicate instrument It was found that by gentle yet firm traction upon the adipose tissue a portion of the capsule would be separated from the viscus This was not uniformly the case, yet occurred sufficiently often to lead me to think it probable that my three sutures included a portion of that structure The difficulties in separating the capsule from the kidney of the patient may not be so great as I found them upon the post-mortem kidney Of this truth I am firmly convinced, great care should be exercised in attempting to seize and separate the renal capsule so as to include portions of it in the sutures My unfortunate experience in the use of carbolized catgut would lead me in another and similar instance to use properly prepared silk in at least one-half of the stitches employed

ON SEPTIC JAUNDICE OF CHILDHOOD, WITH REPORT OF A CASE AND RECOVERY IN CHILD AGED FOUR YEARS

BY M P HATFIELD, M D , CHICAGO, ILL

[Read before the Section on Diseases of Children at Washington Meeting, etc]

Septic jaundice is, fortunately, of rare occurrence among children, for its appearance usually betokens so profound a saturation of the system with septic materials that only the gloomiest prognosis can be given

It is, therefore, a symptom rather than a distinct disease (though sometimes discussed as such under the title of *malignant* or *pernicious* icterus), and deserves careful study as one of the gravest symptoms of toxæmia, concerning whose exact pathology we really know as yet but little

Schiff's experiments, unfortunately not concluded, seem to prove conclusively that the liver acts as the great depurating organ of the body, forming a definite chemical antidote, or chemically neutralizing many of the organic poisons, such as conium when taken into the blood Malarial and septic poisons are doubtless chemically closely allied to these volatile alkaloids and similarly disposed of in the economy, so much so that, as long as the functions of the liver are properly performed, it is very doubtful whether malarial, or septic, intoxication can take place The icteric here so generally found in both of these, as well as in phosphorus and certain other forms of poisoning, betoken the sympathy of an overtasked liver with these forms of toxæmia

Just what the hepatic lesion consists in has not yet been settled The present popular theories would attribute it to small, round, and rod-shaped bacteria filling up the biliary ducts throughout the organ, and thus producing acute yellow atrophy, or something very like it (Hlava) Virchow considers it a metastatic pyæmia, with localized foci Bohn thinks it due to an œdematous condition of the hepatic connective tissue Andral claims that septic icterus originates in an inflammation of the common membrane lining the duct and duodenum, and, with Davidson, believes that the malignant form begins as the catarrhal variety, as does also Cornil Others, and with a fair show of reason, attribute pyæmic jaundice to impressions made upon the nervous system, especially the abdominal sympathetic, by toxic agents, as also happens from fright or protracted mental strain

It is true that division of the splanchnic nerves causes immediate dilatation of the hepatic and other abdominal veins, with consequent alteration of blood pressure in the portal veins, and possible jaundice in this way More probably, if nervous influence plays a part in the production of septic jaundice, it does it indirectly, possibly after this way Septicæmia implies an accumulation of septic material —septin bacteria, reduced hæmoglobin, or whatever may be the peccant material—in the blood in excess of what the liver can dispose of for the safety of the body It is natural to suppose that increased work implies increased functional activity An overworked organ is an irritable one, for *ubi irritatio, ibi flux*, and the metabolic activity of the hepatic cells depends upon the degree of blood pressure Hence, an excess of bile pigment over that excreted both from actual surplus, and possibly from obstruction of ducts by proliferation and fatty degeneration of the hepatic cells Moreover, super-excitation finally leads to exhaustion and paresis of the arteries supplying the organ This produces venous congestion, and this again assists the diffusion of the bile pigment into the circulation At least this seems a reasonable explanation to the writer, and is borne out by microscopic examination, which shows in these cases the hepatic cells shrunken and compressed by young cells, connective tissue and excess of oil globules without nuclei I am aware that this jaundice is considered as hæmatogenous rather than hepatogenous, and due to disintegration of red corpuscles, but this theory I think is gradually losing ground, and is certainly untenable in icterus neonatorum But whatever may be its exact pathology, the disease is certainly a formidable one, according to Frerichs, almost invariably ending in death All treatment, says Murchison, has hitherto proved unsatisfactory, and this must be my excuse for detailing a case with a satisfactory termination, the boy still living among the inmates of the Protestant Orphan Asylum at Chicago, and, up to the time of writing, enjoying as good health as the majority of the other children This case is as follows, and occurred during an epidemic of scarlet fever in the Asylum

---

[1] Ashurst's Surgery, Vol V, p 1096
[2] Ibid

Willie McKeon, æt 4 years, was taken suddenly ill, on the morning of the 4th of August, with sore throat, vomiting and high fever He passed a restless night, and on the morning of the 5th was evidently worse, temperature 104°, and surface of body dusky, with here and there petechial spots about the size of a pea Diagnosis of scarlatina petechials was made with grave prognosis, and on the morning of the third day a true scarlatinal rash appeared The throat became greatly swollen, and the tonsils covered with diphtheritic patches Deglutition was almost impossible and swabbing entirely so, for all medicine administered by the mouth produced vomiting The case now became complicated by the appearance of an entero-colitis, with frequent loose, dark-colored stools and much tenesmus This was however, promptly relieved by the use of starch and laudanum enemata The next morning the child was found very drowsy and delirious, with a temperature of 105°, and the throat sloughing and so fetid that it was hardly possible to remain in the room Antiseptic spray (eucalyptol) with the steam atomizer and quinine, milk and whisky were administered as freely as possible, but, nevertheless, the case steadily continued to grow worse until, on the night of the fifth day, the boy was comatose and deeply jaundiced, with a temperature of 105½° It seemed unlikely that he would live through the night, but the morning of the next day found him still jaundiced from head to foot, and the temperature marking 104° This slight fall from the previous day, and the fact that the diarrhœa was checked were the only symptoms that could be considered in anywise hopeful, and these not sufficient to warrant anything but the gloomiest prognosis for that and the succeeding days (vi vii) during which the child was, if possible, weaker and drowsier than ever during the day-time, with delirium at night Except the use of a nasal douche and an acid quinine bath, treatment was abandoned and the attention of the nurse directed to the administration of whisky and milk enemata, in spite of which the boy was found on the evening of the sixth day speechless, jaundiced intensely, and apparently in articulo mortis The secretions being passed involuntarily in the bed it was impossible to obtain any of the urine for examination, but the stain it left upon the linen showed that it, as well as the nasal mucus and even the cerumen of the ears, was deeply stained with bile pigment As a last resource on the morning of the seventh day oil and mustard were freely applied over the liver, and as the child became a trifle brighter towards night this was followed by the acid pack, so highly spoken of by Beale Recovery after the eighth day was tedious, but uninterrupted except by a parotitis (single), from which the boy at last entirely recovered, and was finally discharged from the hospital exactly one month from the day when he was first taken there, in spite of the hopeless prognoses of all the physicians who had seen him during the progress of what was to them and the writer an entirely unique case For neither Smith, Meigs, Bouchut, Hillier, West, Ellis, Bohn nor Steiner, mention jaundice as a possible complication of scarlet fever, nor give a favorable prognosis in scarlatina petechialis

Septic jaundice, originating from purulent inflammation in the umbilical vessels of the new-born has been exhaustively discussed by Birch-Hirshfeld, [Hdbk der K K Bd iv , ii Abt p 693–702] and others, but septic icterus from other causes is of so rare occurrence that I have been able to find no literature on the subject further than an allusion to its possibility

For the reason previously given, the writer is inclined to believe this a case of septic jaundice due to re-absorption and an effort to eliminate the septic material The case very closely resembled in its clinical aspects one of acute yellow atrophy of the liver In fact, from the symptoms it might have been diagnosed as such, but Niemeyer claims that children do not have acute yellow atrophy, and the final result militates against yellow atrophy which is uniformly fatal, and affords exquisite post-mortem specimens for confirmation of diagnosis As this was wanting in this case, the diagnosis must remain more or less problematic, but the drowsiness and coma were indicative of more than simple catarrhal jaundice; neither were there the clayey stools usual to that form of icterus. Possibly there may have been hæmorrhagic infarcts in the liver, but in that case we should have expected similar hæmorrhage from the bowels. Hence the diagnosis of septic jaundice, and whatever the exact pathological change, the case is certainly interesting and hopeful from its unexpected termination.

SENSATIONALISM AND DOGMATISM IN SANITARY MATTERS.

BY HENRY LEFFMANN, M.D.,
PORT PHYSICIAN AT PHILADELPHIA.

[*Read in Section of State Medicine and Hygiene, American Medical Association, May, 1884.*]

The development of preventive medicine into a full science, to the assistance of which chemistry, microscopy and other aids of research have been invoked, is an event of our own time. This study brings our profession into closer contact with the masses than does perhaps any other department of medicine. The work of instructing the community on sanitary topics has been pushed so far that disease is now generally recognized as the necessary result of violation of natural laws, although some superstitious ideas still survive. The multiplication of official boards of health and the general acquiescence of the public in the decisions of these bodies are so many testimonies to an increased appreciation of hygiene. The medical press, the means by which the profession disseminates its scientific information, is practically unavailable for distributing it among the masses; the intervention of the non-medical press, and especially of the daily newspaper, has been resorted to, and these publications have, within the last few years, dealt largely in articles on sanitation, food adulteration, etc. Now, the daily newspaper is undoubtedly an institution of the greatest value; its shortcomings are entirely overweighted by its benefits, but it cannot be denied that it possesses a strong tendency to sensationalism. Its treatment of sanitary matters has not been free from this defect, and the evil has been increased by a similar disposition on the part of sanitarians themselves. The statements that have been made on some of these questions, both by medical and non medical persons, are unfortunate instances of the danger of a little learning. The public has often been thrown into needless alarm by unwarranted suggestions as to the injurious character of certain substances or special conditions, and violent measures inaugurated for the suppression of imaginary evils.

I remember, for instance, that in my student days sewer gas was regarded as the *fons et origo mali*. I was taught that it was specifically injurious, doubtless the cause of many diseases. I even remember hearing it suggested that it was probably the cause of one class of diseases when it contaminated food, and another class when simply inhaled. Much of this dread has now declined. At a meeting held about a year ago at the College of Physicians, a distinguished sanitary engineer said that the view of the specificity of sewer gas would have to be abandoned; it was probably at most only a carrier of germs.

Great public interest has been attracted lately to two articles of food adulteration—glucose and oleomargarine. That in many cases great deception has been practiced by means of these substances, and that householders, especially among the poorer classes, are daily robbed, cannot be doubted. A desire to prevent such frauds has, however, led to exaggeration in regard to their dietetic characters. There is no reason at all to pronounce them injurious. Glucose, for instance, is practically the form into which cane sugar is converted by the digestive process, and it cannot, therefore, be regarded as injurious. Yet a feeling to the contrary has been allowed to grow to such an extent that a short time ago, when the Business Men's Moderation Society of New York City undertook to certify to the wholesomeness of the beers sold in that city, the officers of the society indicated as one of the objectionable features in the manufacture the use of glucose, and even threatened to make an issue on the question. A certificate has lately been going the rounds of the journals, in which several chemists of reputation jointly declare that glucose is not injurious. As Sir Joseph Porter says, it is the characteristic of this happy country that official utterances are regarded as unanswerable, and so we may hope that the excitement will be stilled, but the facts should have been made known long ago. To object to the use of glucose in the preparation of alcoholic liquors is absurd in the extreme, for it is the form of sugar from which alcohol is nearly always produced in fermentation.

Oleomargarine and its congeners have been extensively assailed, and it seems very difficult to get for it a fair hearing. About six months ago, in a discussion on dietetics before the Philadelphia County Medical Society, a physician of prominence took occasion to allude to the unwholesomeness of these butter substitutes. He gave no reason for his opinion except the dogmatic statement of some French physicians. I took occasion to point out the untenableness of this view, but to no purpose. The first speaker reiterated his opinion, and many of the members seemed to be in accord with him. Yet there is no fact to support this view. Oleomargarine differs from butter in not possessing the derivatives of the more volatile fat acids, especially of butyric. The entire amount of these derivatives is small, and no one has yet pretended that these exert any beneficial or specific action in digestion or nutrition, and the difference, therefore, between the two fats is unimportant. Some of the opponents of the butter substitutes have lately taken refuge in the argument that they may be prepared from impure materials, but this is only an objection to the method. It could be avoided by a proper system of inspection. It is also true that true butter is not always made in the most unexceptionable manner.

Acting probably under the pressure of public excitement on this topic—possibly, however, in deference to the political influence of the dairymen of the State—the New York Legislature has recently framed a bill for the complete suppression of the sale of butter substitutes. In the course of the argument in favor of such a bill, the Legislative Committee say that nitric acid is used for the purpose of depriving the fats of their odor, and they add that nitric acid is a poison. This it certainly is, but it is not likely that a trace of the acid is left in the manufactured product, since any notable quantity would betray itself by taste. The statement must, therefore, be regarded as sensational.

The adulteration of alcoholic liquors is of great sanitary importance, and is a topic on which great errors have been promulgated. Much harm has been done by well-meaning but misinformed temperance leaders, but the tendency of physicians to extol the virtues of fine old genuine liquors has also contributed to a feeling against the factitious articles. These, however, are not, as a rule, more hurtful than the original articles. The substances used in liquor adulteration are mostly non-injurious. I have within the last week had the pleasure to see a recognition of this fact by the physician in charge of the Franklin Reformatory Home in Philadelphia. He refers to the frequent remarks of patients in the Home that their depressed condition was due to the drugs which were put into the liquors, but he emphatically contradicts such a view, and points out that the injurious body in liquor is the alcohol.

There can be no question that a pure water supply is of great importance, but there can be also no question that in some respects water analysis is the quackery of chemistry. It has long been believed that the danger in water was in the organic matter, and various processes have been devised to determine the amount and character of this. Each process has had its turn of favor, and while in fashion has been arbitrarily used as a basis for judging of the wholesomeness of samples. It is curious to notice how the sensational language of certain authorities has become popular in this department of hygiene. The organic matter is rarely spoken of under this simple title. It is called pollution, sewage, organic impurity, etc., all terms calculated to alarm, and by no means always correctly describing its nature.

I might take up the time of the Section with many instances like these. It would be interesting, for instance, to trace the history of the agitation on the subject of alum in baking powders, the use of the agent having been officially condemned as unwholesome and this statement, widely published by a certain baking powder company, is now officially contradicted.

We can see, I think, that there is need in sanitary science for a little of the skeptical spirit, a little of mistrust in dogmatic statements, a little hesitation in accepting the views of any particular authority. It was for the purpose of opposing the tendency to sensationalism and dogmatism that I have brought this paper before the Section.

SACCHARATED VERSUS ALCOHOLIC EXTRACTS.

BY G. C. W.

That many of the more popular quack medicines, tonics and bitters, are essentially alcoholic solutions, varying in percentage of alcohol from eight to about forty-five per cent, has been frequently demonstrated by analytical chemists.

The list published by the State chemist of Rhode Island, giving the alcoholic strength of some thirty or forty of the leading bitters, is familiar to those who have but moderately pursued this line of investigation.

It is not, however, so generally known that the two large classes of staple pharmaceutical preparations, viz.: Elixirs and fluid extracts, are *very rich* in alcohol, the fluid extracts generally containing over fifty per cent. Of these latter I wish now more particularly to speak.

It is doubtless true in the case of those fluid extracts of the more powerful drugs, such as aconite, nux vomica, and the like, that on account of the smallness of the dose, the amount of alcohol administered is insignificant, and, therefore, unimportant as regards physiological effects. But of those where the dose is quite large—and this class is the more employed as compared with those just alluded to—it properly becomes a question of serious importance whether the quite considerable amount of alcohol necessarily introduced into the stomach, enfeebled as it may be, by disease, does not frequently exert an unfavorable effect upon the patient. But even in the event of no prejudicial results directly ensuing, the treatment is usually followed by the highly flavored, often very agreeable, yet strongly alcoholic elixirs of modern "elegant pharmacy," and then as the patient convalesces these are merged into the habitual and frequent use of some one of the popular "tonics" or "bitters" whose special mission too often is, to permanently fasten upon their victim a morbid craving for alcoholic beverages. What physician of long practice but can recall many cases where this order of sequence has been the unfortunate result.

In view of these unhappy results, that, as we know, so frequently occur, it is proper to call attention to the deplorable fact that of late certain unprincipled manufacturers have begun to employ methylic alcohol (wood spirit) to partially replace ordinary (or ethylic) alcohol, and this extremely poisonous substance is doing in many cases most dangerous and deadly work.

Independently, however, of the question of direct action of the alcohol used in pharmaceutical preparations, the friend of sobriety, be he physician or patient, must hail with delight any modification in these products of the pharmacopœia which will render the administration of alcohol unnecessary. Any step taken by pharmacists which demonstrates that other and innocent vehicles may be used as efficient substitutes for alcohol, ought to be welcomed by every one who is not a foe to his race.

We are glad to state that for the staple alcoholic preparations known as *fluid extracts*, a substitute has now for a few years been before the public known as "*saccharated extracts*" These are precise therapeutic equivalents for fluid extracts, have the same dose and are entirely non alcoholic They are substitutes for fluid extracts, with milk sugar as a vehicle instead of alcohol, the former exactly replacing the latter, so that the finished product is a powder instead of a liquid They are made by distilling off the alcohol of a fluid extract at a low temperature, and incorporating with the pasty mass remaining, "solid extract," so much sugar of milk as to bring the strength of the product up to that of the original crude drug, or what is the same, up to the strength of a well-made alcoholic fluid extract of the given drug

The saccharated extract is nearly always soluble in water, and if it is desired to administer the medicine in a fluid form it is simply necessary to give it to the patient dissolved in that solvent And even in the few cases where the particular drug is not capable of entire solution in water, the sugar is dissolved and the drug is left suspended in such a minute state of subdivision as to become very rapidly absorbed when taken into the system—much more rapidly, indeed, than a pill, or many other forms of pharmaceutical preparations Aside from the merits of the saccharated extracts as being non alcoholic, there might be enumerated many advantages which they possess of a therapeutic and pharmaceutical character, which, however, it would be foreign to the scope of this journal to specifically detail We close, therefore, with a quotation simply from the *Journal of Inebriety*

"The introduction of saccharated extracts in the place of tinctures and fluid extracts, has marked a new epoch in the advancement of medicines, which is destined to become very widespread as the profession come to realize the danger from alcoholic extracts and tinctures The Wheeler chemical works, of Chicago, in introducing the *saccharated extracts*, have conferred a favor which will be appreciated by physicians, especially those who have found the administration of fluid extracts and tinctures so dangerous to their patients on account of their alcoholic character"

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS.

On the Therapeutic Properties of Thyme — Dr Campardon has given in the *Bulletin General de Thérapeutique* the result of his practical observations with this drug in some thirteen cases, with the following conclusions

I Internally as well as externally the essence of thyme is a powerful agent producing certain phenomena in the healthy man which are always the same, but vary in degree, according to the dose and constitution of subjects, and which can be divided into three periods

1st The period of excitation

2d The period of super excitation

3d The period of prostration, of collapse, followed by death

II The therapeutic doses are those which produce excitation (from 20 centigrammes to 1 gramme)

III Applied to therapeutics, this drug which is a diffusible stimulant, on account of its exciting properties, should be used internally in chloro-anæmia accompanied by depression, in syncope, etc

IV Its diaphoretic and diuretic properties render it useful in localized muscular rheumatism, in erratic rheumatism, in dermalgia, neuralgia, etc

V Its action on mucous membranes renders it of the greatest utility in the catarrhal stage of affections of the bronchi, the urethra, the vagina, and the bladder

VI It is a hæmostatic and acts promptly and energetically, particularly in passive hæmorrhages

VII Used externally, with friction, baths, fumigations, and inhalations, it is a possible aid to its internal use in shortening the duration of diseased action and in assuring the result

VIII As an antizymotic, its power is equal to that of thymic acid, it is efficacious in counteracting the septicity of wounds, and causes a prompt disappearance of the fœtidity of secretions

Cocaine in the Uncontrollable Vomiting of Pregnancy —Dr M Weiss records in the *Prager Medicinische Wochenschrift*, a case as follows A 28-year old woman being pregnant for the fourth time, was taken with vomiting three weeks after the last appearance of her menses (which was Sept 1), and sought medical advice for its relief at the end of the second month She was found to be much emaciated and anæmic, keeping her bed for the past eight to ten days from debility and persistent vomiting Natural irritability, small but rather frequent pulse Temperature 36 5 C, shallow respiration, faintness on attempting to stand, no organic lesions, third month of pregnancy With the exception of a small quantity of black coffee, hot tea, and mulled wine, no food, even of a fluid consistency, would remain on the stomach No medicines seemed to give any relief, nutrient enemata could no longer sustain life, and the danger of death from inanition became imminent

Nov 7, the cocaine was given as in the following prescription

℞ Cocaine Mur in sufficient quantity of spirit-wine to make a solution of 0 15 Aq Dist 150 0
Sig 1 small teaspoonful every half hour

After the patient at 6 A M had taken a few teaspoonsful of black coffee, an hour later the medicine was given and repeated as prescribed The first doses had a slightly bitter taste which, from the benumbing of the sense of taste, after the third dose was no longer perceptible Some minutes after the sixth dose the patient took 3 tablespoonsful of milk that were well received and not vomited After the eighth dose the patient took with great pleasure a small cup of bouillon with an egg—no vomiting

At 2 P M , 13 to 14 spoonsful of the solution having been taken, the patient was found to be cheerful and bright, and rejoicing over the fact that she had been enabled to retain what she had taken of the midday meal, consisting of broth, a little of the white meat of a chicken and a glass of claret She thought herself well enough to leave the bed The face was somewhat flushed, the pupils moderately dilated, the pulse frequent, increasing from 84 to 96, the respiration from 22 to 28, whilst the temperature in the axilla remained about the same (36 8 to 36 7)

In consequence of these favorable symptoms, the use of the medicine was suspended until 4 P M , at which time the pupil no longer dilated, the pulse fell to 86, the respiration to 22, and the patient again vomited a part of some *cafe au lait* which she had taken Its use was then resumed and kept up until 8 P M , when the patient enjoyed and retained some prepared chicken and a glass of Pilsner beer

Nov 8, the rest of the cocaine solution (about a fourth part) was given in hourly doses There was no vomiting through the day Unfortunately no record was kept of the temperature, pulse, and respiration, so that a comparison with that of the previous day could not be made

Nov 10, the patient left her bed and since then her condition is quite satisfactory She vomits now and again, but retains the greater part of her food She now attends to her usual occupations

ANTIPYRINE —Dr Huchard, in *L' Union Medicale*, has published an admirable resumé of the qualities of this drug, of which the following are his conclusions

1 Antipyrine constitutes a sure and powerful means of lowering the temperature in nearly all febrile diseases (typhoid fever, pulmonary phthisis, pneumonia, pleurisy, acute articular rheumatism and cerebral rheumatism, angiocholitis, erysipelas, diphtheria, puerperal fever, scarlatina, abscess, phlegmons, etc) It lessens the symptoms which are dependent upon the thermic elevation (acceleration of the pulse and of respiration, dryness of the mouth, anorexia, insomnia, etc), but it does not seem to have any direct action upon the respiration and the circulation

2 Antipyrine is an antipyretic, and not an antiperiodic, whence its inefficacy in preventing attacks of intermittent fever

3 Its use does not result in any or but slight disturbances, such as slight sweats, pharyngeal constriction, sometimes nausea or vomiting, and in some relatively rare cases production of rubeoliform or scarlatiniform exanthemata No tendency to collapse, no dizziness, as after the use of the preparations of quinine or salicylates

4 Numerous observations demonstrate that antipyrine constitutes the most powerful means, and at present the only means known of lowering effectually the temperature of cases of tuberculosis

In the dose of 2 grammes, administered more especially in the evening, on the accession of fever, the temperature lowers to half a degree in a half hour, sometimes in a quarter of an hour, after which it diminishes progressively to normal in an hour and a half or two hours It is, however, sometimes necessary to prescribe, one or two hours later, a new dose of 1 or 2 grammes But with phthisical patients antipyrine should be given in feeble and increasing doses (2 to 4 grammes)

5 The antithermic effect continues ordinarily with patients for six to nine hours, and is often felt on the succeeding days, when the temperature does not reach its primitive degree The secondary ascent of temperature proceeds progressively, recalling in this way the progress of defervescence, it is not sudden, and is never accompanied, as with kaisine, by a more or less prolonged chill

6 Antipyrine is eliminated by the urine, where it is recognized two to four hours after its administration, during from thirty-six to forty-eight hours Several drops of perchloride of iron dropped into the urine of patients using the drug, produce immediately a very characteristic red color

7 According to various authors, antipyrine used in typhoid fever must be given in doses of 5 to 6 grammes a day Under the influence of these doses the temperature lowers from the first hour from 0 4 to 2 degrees, continuing in the same proportion to the seventh or eighth hour Frequently at the fifth or sixth hour the temperature rises one degree for about an hour, to again resume its regular descent This slight ascent of temperature during a pyrexia has also been noticed during the use of antipyrine in the fever of phthisis

A CASE OF VAGINISMUS TREATED SUCCESSFULLY WITH HYDROCHLORATE OF COCAINE —Dr Dujardin-Beaumetz reports (*Bulletin General de Thérapeutique*) the case of a servant thirty-three years of age, who was married at the age of twenty one, had a child eighteen months later, with a tedious labor which required the use of the forceps For several months after her confinement she suffered from the effects of a partial retention of the placenta Upon recovery, sexual congress became extremely painful, which was so marked that all cohabitation was impossible Upon admission to hospital and examination, some distance from the orifice of the vagina there was found to be a contractile adhesion strongly marked and resisting the passage of the finger While the patient was under chloroform the vaginal orifice was forcibly dilated, first with the fingers and then with the speculum This operation not proving very satisfactory, a gradual dilatation was attempted by the introduction of the bivalve speculum twice daily, and left in place for one or two hours at a time This treatment proving as inefficacious as the first, painting the internal surface of the labia minora and the whole circumference of the vaginal orifice with a solution of cocaine, 2 parts per 100, was practiced In about a minute sensibility to the prick of a needle had disappeared, and the speculum was introduced almost without any pain, much to the surprise of the patient A second application made on the following day gave the same result On the third day the speculum was introduced without the use of the drug and with but little resulting sensibility After four of such applications, the introduction of the speculum and the practice of the vaginal touch with the finger gave but little annoyance, the contracted adhesion in the vagina being no longer felt

SURGERY.

Reduction of a Dislocation of the Shoulder-Joint by the Kocher Method —M Henrard describes a case in the *Archives Medicales Belges*, of a soldier who presented all the symptoms of a subcoracoid luxation of the right shoulder, falling of the shoulder, prominence of the acromion, the elbow away from the trunk, vicious direction of the axis of the arm, presence of a round and osseous tumor in the axillary space, a depression under the acromion, impossibility to execute the movements of the arm, and slight shortening of the member

According to the patient, this was the sixth time that this accident had occurred Previously recourse was had to different methods, and each time the work of reduction had been very laborious The patient could not give any description of the methods used, because they had been applied under chloroform

The patient was seated on a chair, an aid sustained the affected arm M Ruelle made the reduction On his knee before the patient, he grasped the arm, the fore arm was carried to a right angle, and brought very slowly and quietly, until the elbow was against the trunk This first movement executed, the superior portion of the member in the same gentle way, was rotated outwards The fore-arm was nearly perpendicular to the thorax when the operator and his assistant felt manifestly the movement of the return of the head of the humerus into the glenoid cavity At the same time all the physical symptoms of the luxation disappeared In five minutes the reduction was effected, with hardly any pain to the patient The Kocher method has been described in the January, 1884, number of the *Archives Med Belges*

OBSTETRICS AND GYNÆCOLOGY.

Extra-Uterine Pregnancy—Natural Expulsion of the Child Through the Abdominal Walls—Strangulated Intestine—Artificial Anus—Recovery —Dr Bouzol, in the Lyons *Medical*, reports a case which is fully comprehended under the above title The patient was 38 years of age, and had given birth to six children Her youngest was born June, 1881, and after its birth menstruation was never reëstablished In July, 1883, finding her abdomen enlarging, she suspected pregnancy, and felt movements toward the end of the month These movements were not, however, of the same character as in preceding pregnancies In the first part of December she was taken with pains closely resembling labor pains, which continued to increase in intensity for three days, and then ceased suddenly on the discharge by the vulva of numerous blood clots On December 20 she noticed a decided swelling at the navel, which resulted in a small opening, that discharged a great quantity of yellow liquid for one day, but on succeeding days only a few drops of purulent fluid were passed On January 31, 1884, Dr Bouzol saw her for the first time, found her in bed, much debilitated and greatly emaciated On palpation of the abdomen there was established the presence of a solid, irregular tumor, which passed the median line, but occupied mainly the left plane and internal iliac fossa The tumor was slightly mobile, and extended about a finger's breadth above the umbilicus The umbilicus was retracted, and seemed to be adherent to the tumor, presenting in its centre a small opening, which discharged a little pus, and through which passed a very fine stylet No abnormal sounds on auscultation The tumor was felt through the vagina to be in the left cul-de-sac The doctor prescribed tonics, and left the case to nature, after diagnosticating the true condition of affairs Some days later the umbilicus cicatrized, but at the same time there commenced to develop a little below the umbilicus, and to the left of the median line, five or six prominences unequal in size, which opened spontaneously on February 20, enlarging rapidly and forming a single opening, which was large enough to admit the closed hand Through this opening there passed for fifteen days small bones and pieces of putrefied flesh, terminating in the discharge of two large fragments representing parts of the head After this the abdominal opening cicatrized rapidly until it became of the size of a five-franc piece, and the general health improved accordingly On April 10 the patient made a vigorous effort to get into bed, when a voluminous loop of intestine escaped through the opening This was not returned, but soon became strangulated, with all the accompanying symptoms Dr Bouzol attached, by means of sutures, the intestinal walls to the lips of the abdominal wound, which resulted in the formation of an artificial anus What became of the loop of intestine or how this change was effected the doctor does not tell us very clearly, but says that by the next day all signs of strangulation had passed off, and that a month later the artificial anus was markedly diminished in size, and that the lower extremity of the intestine had commenced to functionate, the fecal matters passing in part through the abdominal orifice and in part through the anus At the present time (December, 1884) the artificial anus is completely closed, leaving behind it quite an apparent cicatrix, which forms a depression in the abdomen

MEDICINE.

On Medullary Scleroses of Vascular Origin —Dr Emile Demarge (*Remede Medecine*) reports at length an interesting case of diffuse syphilitic interstitial myelitis, simulating by the consequent lesions a combined sclerosis of the lateral and posterior columns, vascular in its origin The study of his case leads him to the following conclusions

1 That we must admit a class of interstitial myelites of vascular origin

2 That these myelites have for their initial lesion the endoperiarteritis sclerosis of the vessels of the cord

3 That the dissemination of vascular lesions produce a dissemination and diffusion of lesions of the cord, whence it follows that non systematic but diffuse myelitis is observed

4 That, according to the disposition of the affected points of the cord, the clinical symptoms will be very varied, and simulate the symptoms of lateral sclerosis, of lateral amyotrophic, systematic, combined, and probably still other clinical types

5 That these myelites may have as their cause either syphilis, primitive development in the cord, or be due to a manifestation in the spinal axis of a generalized arterio sclerosis

Medullary scleroses of vascular origin comprise thus

1 Sclerosis in disseminated spots

2 Certain diffused interstitial scleroses, either syphilitic or associated with general atheroma

On Tuberculous Infection through the Genital Passages —M Ch Fernet considers this subject at some length in the *Societe Medicale des Hopitaux* (*Bull et Mem*) formulating his views upon the observation of several detailed cases as follows

1 Primitive genital tuberculosis may probably be caused by direct contagion in sexual intercourse To the numerous sources of tubercular infection as now known or suspected, infection through the genital passages should be added

2 All cases of indolent blennorrhœa, which in certain men follow sexual intercourse, and which are particularly not the result of blennorrhagia proper, should be suspected, many of these cases seem to be of a tubercular nature The same may be said of certain leucorrhœas in the female The appearance of the tubercular microbe in these blennorrhœas and leucorrhœas decides the question

3 Sexual congress with a subject affected with genital tuberculosis exposes one to direct contagion, it involves, then, a risk which it is wise to avoid

4 One of the principal dangers of genital tuberculosis resides in the possibility of a general secondary infection, therefore we should attempt its cure by all means, even in cases of necessity having recourse to operative surgery

On Bacterian Syphilis —Professor Neisser has written an account of this disease which has been considered by P Diday and A Doyon to be of sufficient importance to be translated in full in the pages of the *Annals de Dermatologie et de Syphiligraphie* His propositions are as follows

I *Infection* The bacteria penetrates into the organism by any point upon the surface of the body, where the denudation of epidermis or epithelium allows of their introduction into the lymphatic channels The virus remains at the infected point, certain of the germs pass immediately into the circulation and rest as localized at the lymphatic glands of the infected part

II Then comes the period of first incubation when the presence and action of the bacteria are not manifested, but when they are certainly multiplying at the point of infection and its dependent gland, then follows the primary affection and the engorgement of the primary lymphatic glands

III Invasion of the organism by the bacteria, which are in process of multiplication in the primary affection and in the lymphatic glands

IV The different systems become gradually involved—glands, skin, mucous membrane, etc The glands are the depositories of the bacteria and receive them during what are called the latent periods

V Either these germs disappear finally, and it may be spontaneously, or by the effect of an energetic and persevering treatment, or they persist and in the latter case

VI Relapses occur after periods of latency, when the bacteria penetrate anew in great numbers into the circulation

VII The more recent the period of infection, the greater the number of bacteria in the body and certain of its organs In consequence in the later periods there are

1 Gradual diminution of the influence of infection

2 Gradual diminution of the possibility of hereditary transmission

3 A rarer appearance, and solely in isolated spots, of morbid collections

VIII Moreover, there occurs gradually, perhaps through the influence of accessory chemical products provoked by the bacteria, an alteration of the tissues which constitutes, in the remote periods, the basis of the gummatous forms

IX Mercury is a direct poison to the bacteria, and consequently if it be employed in proper dose and for a sufficient length of time, it should have a preventive action against the appearance of the gummatous period Iodide of potassium accelerates the resorption of neoplasms in small doses for the symptoms at their onset, and in a most striking manner the gummatous products

X As concerns the variable malignity of the disease, it is controlled, making exception of original constitutional abnormalities, viz

1 Principally the quantity of virus which has suddenly invaded the organism, and consequently its evolution depends upon the energy of the treatment

2 Perhaps, also, to the variable quantity of the virus which by the immunity due to a previous infection, and to the heredity of that immunity through several generations, has produced an attenuation

Dr Austin Flint, Jr , adds four more cases of diabetes to the fifty two reported to the American Medical Association The patients were placed on strict antidiabetic diet and Clemens's solution of arsenite of bromine, beginning with three drops, increased to five, was also given Of these four cases three were permanently relieved In conclusion he adds, "*Diabetes has become to day a disease easily and certainly curable, provided that the treatment be not begun too late*"—*Louisville Medical Times*

Congress and a Health Bureau or National Board of Health —As we predicted several weeks since, the committees having charge of the bills relating to national health organizations in the two houses of Congress, have concluded that the time intervening before the 4th of March, is too short to permit the discussion and passage of any such bills

They will, therefore, only recommend the appropriation of $20,000 for the use of the present National Board of Health for the coming year and the placing of $500,000 at the disposal of the President, as a contingent fund, to be used only in case the cholera or other severe epidemic disease should become prevalent in our country during the coming summer and autumn To place an adequate sum of money where it can be used in fighting an epidemic after it has become prevalent, is better than to do nothing Yet, if a cholera epidemic in this country is dependent on the importation of its germs or specific cause, and is therefore preventable by efficient sanitary and quarantine measures, as claimed by sanitarians of the present day, how much more economical and humane would it be, to spend the money in devising and faithfully executing such measures of inspection, detention, and sanitation, both on the sea and on the land, as will be most certain to prevent an outbreak, instead of waiting until the disease is already developed and slaying its victims by thousands, in the midst of suspended commerce and paralyzed industries We do not assert that the prevalent views of sanitarians in regard to the importation of cholera germs and the entirely preventable nature of the disease, are absolutely correct On the contrary, we believe certain meteorological conditions, over which sanitary measures can exert only a limited control, exert an important influence over all severe and widely spreading epidemic diseases For instance, a continuous high summer temperature with little rain-fall, following high water and thorough soil saturation in the early spring, will be accompanied by a high ratio of sickness and mortality from acute zymotic and infectious diseases of some kind If it be not an epidemic of cholera or yellow fever, it will be such an increase of cholera infantum, cholera morbus, dysentery and typhoid fever, as will destroy nearly as many lives in the aggregate as are usually lost by the prevalence of the more dreaded epidemic pestilences The fact, however, still remains, that, while we cannot control the temperature, the rain-fall, and the atmospheric currents—in other words, the meteorological characteristics of the seasons—we can, by rigid cleanliness, soil drainage, free ventilation, and pure water supply, so far modify the effects of these characteristics as to greatly lessen the aggregate of sickness and mortality in any given community or State And this is true, not merely in seasons of expected epidemics, but in all seasons and all countries To ensure the four important conditions first named, the proper sanitary and hygienic measures must be in force and faithfully executed all the time To vote money contingents, to be used only after the high summer temperature has filled the atmosphere with infectious emanations from a soil contaminated with decomposable vegetable and animal matters that have been allowed to accumulate during the winter and been saturated and macerated in the excess of early spring snow and rain falls, until extraordinary sickness is already developed, is very much like authorizing an expensive lock to be put on the stable door after the horses are stolen The most urgently important lesson that needs to be impressed upon the public mind at this time, is, that the same real sanitary measures which are most efficient in either preventing or mitigating great epidemics, such as cholera and yellow fever, are equally efficient in lessening the prevalence and mortality from the most familiar endemic diseases of every season And consequently, that the most economical and efficient use of money for the protection of the public health, is in the constant enforcement of such measures everywhere, as ensure the most perfect cleanliness, the least accumulation of organic decomposable material in the soil, the best drainage and ventilation, and the purest water supply

American Medical Association and the Railroads —Since the announcement was made, in the

January 31st issue of this JOURNAL, in which it was stated that the Illinois Central Railroad would run a special excursion train of Pullman Palace Cars from Chicago through to New Orleans, leaving the former city at 9 P. M. of April 25, making the trip in thirty-six hours, we have been apprised that an arrangement has been made with the general passenger agents representing the various roads leading to the Crescent City, that the prospects for a magnificent trip are very bright whereby members and their families going south, via the Illinois Central route, will be enabled to return via Mobile, Montgomery, Nashville, Mammoth Cave and Louisville, over the Louisville & Nashville line, or via Meridian, Chattanooga and Cincinnati, over the Cincinnati, New Orleans & Texas line (Queen and Crescent route), or those who prefer may be returned by boat on the Mississippi River as far as Natchez, Vicksburg, Memphis, Cairo, St. Louis, etc.

Round trip tickets will be issued and can be purchased in Chicago for any of these routes, which may be selected at time of purchase.

It is safe to announce that the rates will be very low, and the tickets will be good for thirty days, with stop-over privileges. The sleeping-car fare, also, it is expected, will be considerably reduced from the regular rate.

All of which will be an inducement for a very large attendance of members living adjacent to this through line, and from the North and Northwestern States, to attend the coming meeting of the American Medical Association, and to visit the World's Fair, that is in progress in New Orleans, which does not close until May 31.

IS THE tolerance of large doses of medicine in certain cases of disease proof that such medicine is indicated?

This question, which was briefly discussed in a previous number of the JOURNAL, has elicited a reply from Dr. Batten, of Pittsburgh, whose letter may be found under the head of Domestic Correspondence. He thinks there is abundant evidence to justify answering the question in the affirmative, but adduces only the well known fact that the more pernicious cases of malarial fever require large doses of quinine, the rather curious allegation that patients with yellow fever demand large doses of quinine and calomel, and that cases of diphtheria tolerate very large quantities of alcohol in the form of whisky and brandy without dying. We suppose quinine is indicated in the treatment of all forms of malarial fevers, not because it is tolerated without apparent effect in either small or large doses, but because clinical experience has shown that it is capable of either neutralizing the malarial poison direct, or of indirectly counteracting its effects on the properties of the blood and tissues. That much larger doses are required and tolerated in the pernicious cases only shows that the malarial poison has so profoundly depressed the susceptibilities of the tissues, that they are capable of responding but feebly to the presence of the quinine, until by other agencies such susceptibilities have been aroused and reaction commenced. The tolerance of unusual doses, therefore, simply indicates diminished sensibility to the action of the drug, and clearly suggests the necessity for the employment of other agents to reestablish such sensibility before the quinine can display its beneficial action in any degree. The same explanation applies to the tolerance of large doses of alcohol in diphtheria, which is a disease preeminently characterized by such alterations in the properties of the blood and the molecular-movements and susceptibilities of the system as to render the patient much less susceptible to the action of alcohol and some other agents, especially during its active stage, than in health. Such want of sensibility to its action, however, neither constitutes proof of its curative influence, nor that a large accumulation of it in the system is not liable to produce injurious and even fatal effects in the declining stage of the disease. Not a few cases have been reported of sudden death from paralysis of the heart after the patient was supposed to be approaching convalescence, and that, too, while they had a full supply of the alcoholic remedies. The points we made before, and repeat now, are: First, that tolerance of unusually large doses of remedial agents in any given case instead of proving such agent to be beneficial really proves a want of susceptibility to its action, and should point us to other agents better adapted to such morbid conditions; and second, that the saturation of the system with very large doses of active medicinal agents during the active stage of acute, self-limited diseases, when the susceptibility of the tissues or sensibility of the nervous systems are blunted, is liable to have a dangerous accumulation of such agents in the system on the decline of the morbid conditions belonging to the disease.

RUSH MEDICAL COLLEGE COMMENCEMENT.—The regular Annual Commencement exercises of the Rush Medical College, of this city, took place in Central Music Hall, on the afternoon of Feb. 17th, 1885.

The Hall was well filled with an appreciative audience, and the ceremonies were of the usual formal and imposing character The degrees were conferred by the President of the College, Prof J Adams Allen, and the general valedictory address was delivered by Prof W H Byford From the report of the Secretary of the Faculty, Prof J H Etheridge, we learn the whole number of students attending the past College term was 401, and the number on which degrees were conferred was 151, the length of the College term, a little less than five months

Dr Thomas N Reynolds, of Detroit, Professor of Materia Medica, Therapeutics and Clinical Medicine in the Detroit Medical College, died at San Antonio, Texas, February 14, from hæmoptysis He was born at Meaford, Ontario, February 2, 1843 He had been for a number of years a member of the American Medical Association He leaves two brothers, Dr Henry J Reynolds, and Dr Arthur R Reynolds, well known physicians of this city, whose loss is an irreparable one

SOCIETY PROCEEDINGS

CHICAGO MEDICAL SOCIETY.

At the regular meeting of this Society, held on the evening of February 2, 1885, Dr Boerne Bettman read a paper entitled "Peroxide of Hydrogen in Aural and Ophthalmic Practice" The essayist remarked that the antiseptic measures introduced by Lister had been applied in aural therapeutics, and marked the era of rational medication in otology Carbolic acid, although highly satisfactory as a cleansing agent, could not be applied as a germicide, a 5 per cent solution not being tolerated by the sensitive mucous membrane The boracic acid treatment of Bezold, therefore, immediately found many advocates, it has well sustained the severe tests to which it has been subjected Happy results have also been achieved with bichloride of mercury and iodoform A remedy equally efficient, and very useful in cases where the others have failed, is the peroxide of hydrogen, discovered by Thenard in 1818, and introduced into medical literature by Dr B W Richardson, of London, in 1855 It soon fell into disuse, to be entirely forgotten, but it has lately been reclaimed by the unceasing labors of Dr Coffin, several Parisian surgeons, and by Dr W A Harlan, of this city It has been principally employed by dentists in the treatment of alveolar abscesses But few allusions have been made to it in ophthalmic and aural literature The usual method of preparing pure peroxide of hydrogen, is by decomposing peroxide of barium with hydrochloric acid It is a highly prized antiseptic In a pure state it is a colorless, syrupy liquid, of a slightly bitter taste, and possesses a faint odor of chlorine Its specific gravity is 1 455 It is a highly unstable compound, decomposing rapidly when exposed to air, and liberating its oxygen It owes its value as a therapeutic agent to this property M Miguel, of the Observatoire de Montsouris, in his comparative table presenting the relative value of the various antiseptics, places peroxide of hydrogen at the head The writer then related his observations, made with the microscope, of the action of dioxide of hydrogen upon pus The pus corpuscles and bacteria are put into lively motion, when a drop of peroxide is allowed to flow under the covering glass Small gas bubbles, the liberated nascent oxygen, are now evolved The pus corpuscles gradually lose their spherical shape, shrink, assuming a crescentic form, and are heaped together a mass of detritus The bacilli are affected in a similar manner In a few seconds they are transformed into a dead mass, intermixed with the decomposed pus corpuscles, and surrounded by seething bubbles of gas The therapeutical action of peroxide of hydrogen has been explained as follows Where it comes in contact with pus the extra O it contains is liberated so rapidly that the hydrogen and sulphur of the tissues immediately combine, resulting in H_2SO_4 in small quantity, sufficient to glaze the pus-producing area, thus affording an opportunity for the exuding protoplasmic material to organize into new tissue The remaining unsatisfied atoms of O quickly distend the pus sack and force out the contents He has used the remedy in more than thirty cases of otitis media purulenta, and employs a preparation sold by chemists as containing 12 volumes of the gas, as follows The parts are thoroughly cleansed with warm water and then dried with absorbent cotton, after which 8 to 12 drops of the remedy are instilled into the ear Contact with pus and diseased tissues sets free the oxygen visible as bubbles, which united with the expelled pus forms a seething, frothy mass Patients rarely complain of pain After cleansing the parts, the mucous membrane is seen to have assumed a milky white appearance The liberated gas enters the most hidden recesses of the middle ear, forcibly dislodging the decomposing material, and destroying bacteria embedded in the tissue meshes If the perforation is small the remedy can be injected directly into the middle ear It has also been successfully employed in the treatment of dacrocystitis, and in one case of chronic trachome which had run its course, but where there still remained a mucid discharge Several (5) cases of dacrocystitis yielded only to the peroxide of hydrogen after having been subjected to the routine medication with astringents, carbolic acid, introduction of Bowman's probe, and gelatine bougies

In the discussion, Dr R Tilly stated that he had seen the peroxide of hydrogen solution used in Paris by Palse as a spray in ovariotomy, and also by Laudolt in dacrocystitis, but saw no manifest advantage from its use that should entitle it to a position of preference over certain well known and well-tried remedies, among which he mentioned permanganate of potassium solution In observations with the preparation, it was of considerable importance to ad-

January 31st issue of this JOURNAL, in which it was stated that the Illinois Central Railroad would run a special excursion train of Pullman Palace Cars from Chicago through to New Orleans, leaving the former city at 9 P M of April 25, making the trip in thirty-six hours, we have been apprised that an arrangement has been made with the general passenger agents representing the various roads leading to the Crescent City, that the prospects for a magnificent trip are very bright whereby members and their families going south, via the Illinois Central route, will be enabled to return via Mobile, Montgomery, Nashville, Mammoth Cave and Louisville, over the Louisville & Nashville line, or via Meridian, Chattanooga and Cincinnati, over the Cincinnati, New Orleans & Texas line (Queen and Crescent route), or those who prefer may be returned by boat on the Mississippi River as far as Natchez, Vicksburg, Memphis, Cairo, St Louis, etc

SOCIETY PROCEEDINGS

CHICAGO MEDICAL SOCIETY.

At the regular meeting of this Society, held on the evening of February 2, 1885, Dr Boerne Bettman read a paper entitled "Peroxide of Hydrogen in Aural and Ophthalmic Practice" The essayist remarked that the antiseptic measures introduced by Lister had been applied in aural therapeutics, and marked the era of rational medication in otology Carbolic acid, although highly satisfactory as a cleansing agent, could not be applied as a germicide, a 5 per cent solution not being tolerated by the sensitive mucous membrane The boracic acid treatment of Bezold, therefore, immediately found many advocates, it has well sustained the severe tests to which it has been subjected Happy results have also been achieved with bichloride of mercury and iodoform A remedy equally efficient, and very useful in cases where the others have failed, is the peroxide of hydrogen, discovered by Thenard in 1818, and introduced into medical literature by Dr B W Richardson, of London, in 1855 It soon fell into disuse, to be entirely forgotten, but it has lately been reclaimed by the unceasing labors of Dr Coffin, several Parisian surgeons, and by Dr W A Harlan, of this city It has been principally employed by dentists in the treatment of alveolar abscesses But few allusions have been made to it in ophthalmic and aural literature The usual method of preparing pure peroxide of hydrogen, is by decomposing peroxide of barium with hydrochloric acid It is a highly prized antiseptic In a pure state it is a colorless, syrupy liquid, of a slightly bitter taste, and possesses a faint odor of chlorine Its specific gravity is 1 455 It is a highly unstable compound, decomposing rapidly when exposed to air, and liberating its oxygen It owes its value as a therapeutic agent to this property M Miguel, of the Observatoire de Montsouris, in his comparative table presenting the relative value of the various antiseptics, places peroxide of hydrogen at the head The writer then related his observations, made with the microscope, of the action of dioxide of hydrogen upon pus The pus corpuscles and bacteria are put into lively motion, when a drop of peroxide is allowed to flow under the covering glass Small gas bubbles, the liberated nascent oxygen, are now evolved The pus corpuscles gradually lose their spherical shape, shrink, assuming a crescentic form, and are heaped together a mass of detritus The bacilli are affected in a similar manner In a few seconds they are transformed into a dead mass, intermixed with the decomposed pus corpuscles, and surrounded by seething bubbles of gas The therapeutical action of peroxide of hydrogen has been explained as follows Where it comes in contact with pus the extra O it contains is liberated so rapidly that the hydrogen and sulphur of the tissues immediately combine, resulting in H_2SO_4 in small quantity, sufficient to glaze the pus-producing area, thus affording an opportunity for the exuding protoplasmic material to organize into new tissue The remaining unsatisfied atoms of O quickly distend the pus sack and force out the contents He has used the remedy in more than thirty cases of otitis media purulenta, and employs a preparation sold by chemists as containing 12 volumes of the gas, as follows The parts are thoroughly cleansed with warm water and then dried with absorbent cotton, after which 8 to 12 drops of the remedy are instilled into the ear Contact with pus and diseased tissues sets free the oxygen visible as bubbles, which united with the expelled pus forms a seething, frothy mass Patients rarely complain of pain After cleansing the parts, the mucous membrane is seen to have assumed a milky white appearance The liberated gas enters the most hidden recesses of the middle ear, forcibly dislodging the decomposing material, and destroying bacteria embedded in the tissue meshes If the perforation is small the remedy can be injected directly into the middle ear It has also been successfully employed in the treatment of dacrocystitis, and in one case of chronic trachome which had run its course, but where there still remained a mucid discharge Several (5) cases of dacrocystitis yielded only to the peroxide of hydrogen after having been subjected to the routine medication with astringents, carbolic acid, introduction of Bowman's probe, and gelatine bougies

In the discussion, Dr R Tilly stated that he had seen the peroxide of hydrogen solution used in Paris by Palse as a spray in ovariotomy, and also by Laudolt in dacrocystitis, but saw no manifest advantage from its use that should entitle it to a position of preference over certain well-known and well-tried remedies, among which he mentioned permanganate of potassium solution In observations with the preparation, it was of considerable importance to adhere to the tendency of the most careful workers of the day, and ascertain to just what factor of the peroxide solution the alleged virtue was attributable It is a fact that the peroxide of hydrogen solution is rendered more permanent by virtue of an acid, and the acid used is sometimes hydrochloric, and sometimes sulphuric acid is used, the former being more generally selected at the present time The quantity of acid used is very small, but small as it is, it may have considerable influence It should always be ascertained by the person using it which of the acids is used to facilitate the solution of the peroxide, as minute quantities of sulphuric acid may have very deleterious effects in certain cases The best test for the presence of the peroxide in solution is a crystal or two of permanganate of potassium

Dr W W Allport stated that he had used this remedy in alveolor abscesses and pulpless teeth On filling a cavity of a tooth with the solution, effervescence occurs and assists the cleansing of the cavity

Dr J S Marshall has treated burrowing abscesses when for obvious reasons he did not wish to make an external opening By injecting a solution freely into such a cavity, the relief was much more rapid and satisfactory than with other agents he had used

Dr G Newkirk has used it in cases which were not blind abscesses, and obtained satisfaction He found it difficult to obtain the substance reliable, and to keep it good

Dr Bettman consented to the suggestion of the last speaker that it does not keep well, and that it is of importance to obtain a reliable article He felt sure that its effect on pus was due to the liberation of oxygen when it comes in contact with pus and its associated products

Missed Abortion, by Dr P O'Connell, was the title of the next paper, in which he recited a case, notes of which cover a period of two years The patient was twenty-six years old, and had one child two years old Three months after her last confinement the catamenia appeared This function continued to come on regularly for several months, when it ceased In addition, the other usual symptoms of pregnancy were present Three months from the commencement of pregnancy the patient fell, striking rather heavily on her hands and knees A slight sanguineous vaginal discharge, lasting a few hours, followed the fall After this the abdomen, which had been enlarging, slowly diminished to its normal state, and her health slowly but steadily deteriorated She had almost constant aching, with occasionally a severe pain, and a sensation of the limb "going to sleep" was felt in the left lower extremity She could not lie on the left side

Careful palpation of the hypogastrium gave no evidence of uterine enlargement The left vaginal region was tender on deep pressure On vaginal examination, the finger met the uterus fully one inch lower than normal, with the os and cervical canal *so* patent as readily to admit the index finger The anterior segment of the cervix was thickened Upon bimanual examination, the uterus was found to be somewhat enlarged, but in no wise sensitive

The sound penetrated to a depth of 2½ inches, and to the left There was no hyperæsthesia of the vagina, although its mucous membrane was congested The cervix was also congested and bled freely and readily Ergot and strychnia were prescribed, and soon after the first dose was taken uterine contractions set in, resulting in the expulsion of the mass which was greatly decomposed and abominably ill smelling It had doubtless laid in utero for three months Upon close questioning the patient she said that during August, which was extremely hot part of the time, she frequently felt so cold at night as to require heavy bed coverings to keep warm That she had frequent chills, and once had what would seem a rigor These symptoms with itching, an erratic rash on the skin of the lower abdomen and back, together with malaise and slowly increasing debility clearly pointed to the absorption of septic matter from the cavity of the uterus The pain in the left lower extremity was due to the dead weight of the uterus on the branches of sacrel plexus of nerves The specimen was then exhibited which presented a mummified appearance and consisted of the placenta and two fœti

Muriate of Apomorphia in Chronic Bronchial Asthma, with a report of two cases, is the subject of a paper read by Dr G W Webster

CASE I —Mr G —English, 34 years of age, married, carpenter, has suffered from bronchial asthma, for more than one year He has been a resident of the United States about two years and three months During the past summer, especially at night, he suffered greatly from this difficulty When first called to attend him in December last, he was suffering from asthma and severe attacks of spasmodic coughing spells, and he had been for some days confined to his bed Gave him remedies to overcome the difficulty which did not in some respects afford him the least relief

Apomorphia per orem in gr $^1/_{30}$ every three hours, was given him And the following morning the patient stated that he passed a comfortable night The remedy was then increased to $^1/_{10}$th gr ter die, and the second night he slept well and rested comfortably from this time on whilst taking the drug It was then discontinued, but the attacks recurred, however, with much less severity The remedy was again renewed and with entire relief It was then given him for two weeks, during which time he was up and about and able to follow his trade

It is now four weeks since he ceased taking the drug and there has been no return of the disease

CASE II —Mr B, aged 58, laborer Has had chronic bronchitis with asthma every winter for many years When called to see him in January, found him suffering greatly from dyspnœa, rales were present over the entire chest, and his face and hands were cyanosed, and he was gasping for breath Gave apomorphia in $^1/_{20}$ gr doses every three hours, and the subsequent day he was considerably relieved and could breathe freely The remedy was continued a few days longer with continued relief to the patient, since which the writer had not seen him

D C T Fenn referred to a mismanaged case of "frost bite," and alluded to the ill usage of two of our most efficacious remedies, viz , ice and heat, by their being misapplied at the proper time

Dr R E Starkweather distributed a number of bound volumes of the sixth annual report of the Illinois State Board of Health

The Society then adjourned

LISTON H MONTGOMERY

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, February 5, 1885 The President, B F Baer, M D , in the chair

Cervical Pregnancy —Dr E E Montgomery read a paper in which he recounted the history of a case seen by him in consultation with Dr Alexander The patient had been pregnant eight times, the last labor had been terminated by forceps The present pregnancy had lasted three months when she was taken with severe pain and quite profuse hæmorrhage An examination under ether disclosed that the cervix was distended, forming a globular tumor The os, turned backward, was filled up with a tense membrane breaking through it, the cervix was found to be a large cavity in which was the fœtus and its envelopes The body of the uterus appeared like an excrescence upon the distended cervix, it would admit a finger, and was lined by a decidua The membrane below was continuous with the outer mucous membrane of the cervix, so that the remains of it hung as a fringe from the os

This case differed from the few cases of this condition described, in that there was no contraction of the os, in the majority of cases it occurs in primiparæ, and when discovered it was necessary to proceed to artificial measures to make an opening (*The paper will be published entire in the New York Medical Journal*)

Dr Goodell remarked that he had no knowledge of cervical pregnancy One case which had been sent to him as such was epithelial cancer of the cervix How could such a case be diagnosticated without a post mortem examination? Dr Montgomery's hypothesis of an arrested abortion is probably the correct solution of such a case as he has described The fœtus might be forced out of the body of the uterus, and arrested in the cervix by an unyielding os or by cicatricial bands Some years ago a physician of this city, who had a large obstetrical practice, borrowed his ecraseur for the removal of a supposed uterine polypus which proved to be a fœtus in its amniotic sac Dr Goodell had never been able to understand how an experienced man could make such a mistake, but the description of this case of cervical pregnancy has thrown light upon the matter Dr Montgomery's description of the distended cervix would apply very well to uterine polypus with a long pedicle, and a mistake in diagnosis might easily be made

Dr Montgomery questions the primary occurrence of cervical pregnancy He believes the fœtus had originally taken its seat in the body of the uterus and had been forced into its lower position later, but it might be primary, the internal os being patulous, the same conditions that sometimes cause placenta prævia might cause the entire fecundated ovum to be arrested in the cervix

Ruptured Uterus —Dr B F Baer presented the specimens and related the history (which will be found in full in the *American Journal of Obstetrics*) Mrs F , colored, 32 years of age, married ten years, had borne four children at term and had one miscarriage The first child was forceps delivered and was still-born Nov 14, 1884, she was taken in labor A midwife in attendance who pronounced everything correct After a few hours of severe pains, the patient "felt something break in the womb" and labor ceased, but was replaced with sharp pains all over the abdomen, blood escaped in great quantity from the vagina Collapse ensued, and she was thought to be dead, a slow reaction occurred and her attendants waited for labor to begin again Dr Fisher was called to see her ten days after the accident He found her abdomen tender and tympanitic, a mass like the head of a fœtus in the right hypochondriac region The pelvis was empty Temperature, 103° pulse, 108 and small Rupture of the uterus, and escape of the fœtus into the abdominal cavity was diagnosticated Dr Baer was called in and confirmed the diagnosis The patient refused operative assistance and preferred to die in peace, but five days later asked to be relieved Preparations were made for laparotomy An examination per vaginam revealed a gangrenous pus escaping freely and the placenta loose and hanging from the vagina, the hand passed readily through the os uteri and through a tear in the right wall of the cervix into the abdominal cavity and came upon the trunk of the child The latter was extracted through the vagina by version by the feet, it was putrid The parts were well irrigated with carbolized water, and the hand again introduced entered an adventitious sac and nowhere came in contact with intestines or other viscera The uterus was well contracted and quite small The uterus and sac were washed out with carbolized water until it returned pure The patient died of septicæmia ten days after the removal of the fœtus Dr Baer is in full accord with the principles advanced by Dr R P Harris in his paper entitled, "*If a woman has ruptured her uterus during labor, what should be done to save her life?*" *Amer Jour Obst*, *Oct*, *1880*, *p 809*, in which he advises that the abdomen should be opened and the peritoneal cavity thoroughly cleaned In this case, however, nature had protected herself by forming an adventitious cavity, and there could be no reason to open the abdomen to clean this out, as it could be reached from below more directly and without injury to the soft parts

Dr Henry M Fisher —In Germany a distinction is made between lymphatic septicæmia and phlebitic septicæmia In the first form the poison is absorbed by the lymphatics, and inflammation of serous surfaces with exudation is the consequence In the phlebitic form numerous emboli are formed, and hectic fever and local pus formations, the result of these emboli, are found At the autopsy, in this case, pleural and pericardial effusion was found It will be remembered that peritonitis occurred very soon after the rupture

Dr Goodell remarked that he had come intending to criticise Dr Baer's treatment of this case for not resorting to laparotomy, but he found himself agreeing with both Dr Harris and Dr Baer In recent cases laparotomy should always be performed, but in fifteen days an adventitious sac had been formed, and the danger to the patient would have been increased by operation He had seen two cases of rupture of the uterus Both of them occurred in the practice of a physician who never used obstetric forceps, and who had to send four miles for a consultant In the first case peritonitis rapidly supervened, the abdomen became very much enlarged and the fœtus could not be located by palpation The abdomen was not opened After long groping the fœtus was found close under the diaphragm He had great difficulty in extracting it, as the loops of intestines became entangled between its legs, the placenta was also found in the abdomen In the other case the body of the fœtus had escaped into the abdomen, but the head was still in the uterine cavity it was delivered by forceps Both patients died In both cases it would have been far better to have opened the abdomen (*Amer Jour Obst*, Vol x, 1877, p 478)

Dr Harris is in accord with Drs Goodell and Baer as to the proper treatment of the case reported It was too late to do anything when the physician was called The general opinion is coming around to coincide with his way of thinking concerning the propriety of laparotomy in all cases as soon as reaction from the shock of rupture and hæmorrhage has been established Of the cases reported, after such treatment, 50 per cent have recovered One woman has been reported as having ruptured uterus in four successive labors, with delivery per vaginam and without laparotomy, and she survived it all, but such a case is phenomenal Three cases in Europe have been treated by removal of the uterus, as in the Porro operation, they all died There seemed to be no reason for such a method In most cases the split extends through the cervix, and thus free drainage from the abdominal cavity is secured One reason for closing the cervical rent by sutures, is to avoid the danger of cancerous growths, to which that lesion is supposed to give rise

Dr Longaker remarked that many of these cases died from the profound shock and hæmorrhage immediately following the accident Two cases in his experience had died within two hours, one of them undelivered

Dr Baer was glad to hear Dr Harris make the distinction as to the propriety of laparotomy in his case, where the patient was not seen until fifteen days after the accident and was suffering from septicæmia He had intended to perform laparotomy, and was prepared for it, but when he found the newly developed sac he changed his plan, as he thought nothing could be gained by it

Ovarian Cysts —Dr Baer exhibited two ovarian cysts Mrs B, widow, entered my private hospital December 18, 1884 She commenced eight months before to suffer from frequent calls for micturition, with severe scalding pains, symptoms apparently of cystitis and urethritis The uterus and ovaries were in good position, and seemed normal, but two weeks later there was a burning pain in both ovarian regions, with a perceptible bulging, largest on the right side The menses had ceased, and the doctor in attendance suspected pregnancy, but exposure was denied at that time The abdomen enlarged rapidly, and the patient finally acknowledged the possibility of pregnancy, and thought she felt movements of the fœtus. At seven months uterine hæmorrhage commenced, and continued every day, the mammæ were atrophied, there were no signs of the presence of a fœtus, there was some fluctuation, the sound was passed, and the uterus was found empty, and not enlarged, the face was wasted, and had an anxious expression, and the pulse was quick A diagnosis of ovarian cyst was now made A deep, diagonal sulcus could be made out in the abdominal tumor, the largest portion being on the right side, the tumor was smooth surfaced and without nodules The cervix was soft, patulous, high up, and drawn to the left. When the tumor was moved the uterus moved with it, as shown by the handle of the sound Immediate operation was advised and performed Incision three and one-quarter inches, two large tumors were revealed, both were tapped, the left which was free from adhesions, was withdrawn without difficulty, its pedicle transfixed, ligated and dropped The larger tumor, although free from abdominal adhesions, could not be drawn out, and it was found to be very tightly adherent to the uterus. which seemed to be one mass with it As the fluid drawn from this tumor was clear, it is not improbable that it was a cyst of the broad ligament It became necessary to enucleate the cyst, and a long gaping wound was left in the broad ligament, this was transfixed and tied as a pedicle, but after the final division had been made the ligature slipped and the hæmorrhage was immense, the hæmastatic forceps were applied temporarily, and the bleeding points were firmly secured The wound in the broad ligament was closed by ten interrupted sutures The operation lasted two and a half hours, the patient collapsed, and he feared she would die on the table, but she reacted, and recovery was uninterrupted, the patient sat up in two weeks An incident which occurred on the fourth day shows the necessity of the proximity of a physician or thoughtful nurse A scream from the patient, an announcement of a sudden pain on the right side, the patient said something seemed pulling inside of her Dr Baer was near, and was called He feared internal hæmorrhage, but at once inquired how long it had been since she had passed water, four hours, the catheter was immediately used, and complete relief was secured After this the catheter was not required until the tenth day, but from the tenth to the twentieth day there was entire inability to pass water except by the assistance of the catheter She went home on the twenty-third day

The points of special interest in this case are

1st The patient being entirely well, symptoms of gonorrhœa presented themselves, and were followed by—

2d Amenorrhœa for seven months, followed by—

3d Daily hæmorrhages for one and a half months

4th Ovaritis and large tumors forming in eight and a half months from the initial symptoms

Dr Beates —A young lady was obliged to separate from her husband one month after marriage in consequence of domestic trouble, her menses continued regular, but her abdomen enlarged as rapidly as if she were pregnant, her health failed, and at the expiration of nine months an ovarian tumor was removed, recovery was complete and rapid

In another case he found numerous omental and enteric adhesions which were easily separated, but pelvic adhesions required enucleation of the cyst, which left a large V shaped wound in the broad ligament, as described by Dr Baer Hæmorrhage was very free, in trying to dissect off the tumor from the fundus of the uterus, that organ was badly wounded, the cavity was opened, and required to be closed by sutures Great tympany followed this operation, and breathing became almost impossible, the patient recovered

Calculi in the Female —Dr J W Snowden exhibited the stones and related the history of the case He was called, June 1, 1884, to see Mrs L aged 23 years She was born and had resided in a limestone region in New York Up to 13 years of age she was troubled with enuresis, wetting the bed almost nightly After this she ceased passing her urine during sleep, but was obliged to rise for this purpose two or three times during the night She could not retain her urine night or day after the desire to pass it came on If she could not reach a convenient place she would wet her clothes

She married when seventeen years old Two months after marriage she began to have cystic irritation and soon passed sabulous matter and small calculi These symptoms continuously increased Physicians whom she consulted said she had catarrh of the bladder, but none made an examination for stone Once she was obliged to call on a medical man to remove a calculus which had become impacted in the urethra

Two years ago she spent a summer in New Jersey, during which time she passed no gravel but the irritation of the bladder continued When I first saw her she was urinating very frequently with more or less pain She passed stones daily with a great deal of sabulous matter The urine looked as if there was a quantity of ordinary sand in the bottom of the vessel I proposed an examination for stone, which she refused peremptorily I gave her benzoic acid, which entirely stopped the passage of the sabulous matter and relieved her in every way, but she still occasionally passed a small calculus This marked relief lasted two or three months, when the irritation of the bladder became worse than ever She could only pass her urine in an erect position and with as much effort as a woman in labor I insisted upon an examination for stone, but the slightest touch excited such intense pain, even when she was well etherized, that, being alone, I could not manage her and I sent for Dr B F Baer in consultation

A calculus measuring about one and a half inches in its longest diameter was found in the bladder and removed by Dr Baer after rapid dilation of the urethra This afforded marked relief and she soon seemed entirely cured, but in a short time her urine began to dribble continually while she was in the recumbent position at night During the day she retained and passed her urine naturally I advised her to get up at stated intervals and empty her bladder, which has gradually relieved this trouble She is now quite well, except that she urinates rather more frequently than is natural

STATE MEDICINE

AMERICAN PUBLIC HEALTH ASSOCIATION.

SECRETARY'S OFFICE, CONCORD, N H, Jan 7, 1885

PRELIMINARY CIRCULAR —The thirteenth annual meeting of the American Public Health Association will be held at Washington, D C, December 8–11, 1885

The executive committee have selected the following topics for consideration at said meeting

I The best form in which the Results of Registration of Diseases and Deaths can be given to the Public, in weekly, monthly and annual reports

II The proper Organization of Health Boards and Local Sanitary Service

III Recent Sanitary Experiences in connection with the Exclusion and Suppression of Epidemic Disease

IV Healthy Homes and Foods for the Working Classes (See Lomb Prize Essays)

V The Sanitary Conditions and Necessities of School Houses and School Life (See Lomb Prize Essays)

VI Disinfection and Individual Prophylaxis against Infectious Diseases (See Lomb Prize Essays)

VII The Preventable Causes of Disease, Injury and Death in American Manufactories and Workshops, and the best means and Appliances for Preventing and Avoiding them (See Lomb Prize Essays)

All persons who propose to present papers at the next annual meeting (prize essays excepted as per conditions elsewhere given) must place the same in the hands of the Secretary at least three days before the commencement of the annual session, as such papers must be examined by a committee before being read This rule will be rigidly enforced, and all authors must be governed by it After Dec 1, 1885, papers must be sent to the Secretary at Washington, D C, care of Dr Smith Townshend, Chairman Local Committee of Arrangements Active and associate members have equal rights in the presentation and discussion of papers The Local Committee of Arrangements is already organized, and active work begun to make the next meeting a large and successful one

The generous prizes offered by Mr Henry Lomb will tend to awaken an increased interest in the great work which this Association has for years been successfully prosecuting, and will add much to the already more than national reputation of its beneficent undertakings

The cooperation of all persons interested in the public health, or in any subject allied to sanitary science, is respectfully solicited A circular giving full and concise information regarding local matters, programme, transportation, etc , will be issued in due season before the meeting

The Lomb Prize Essays —Mr Henry Lomb, of Rochester, N Y , has offered through the American Public Health Association, the sum of two thousand eight hundred dollars, to be awarded as first and second prizes for papers on the following subjects, and according to conditions mentioned elsewhere

I Healthy Homes and Foods for the Working Classes First prize, $500 , second prize, $200

Essays to be of a practical character, devoid as far as possible of scientific terms They must be within the scope and understanding of all classes, and designed especially for a popular work

Judges —Dr E M Moore, Pres State Board of Health, Rochester, N Y , Dr C W Chancellor, Sec'y State Board of Health, Baltimore, Md , Medical Director Albert L Gihon, U S Navy, Washington, D C , Dr J H Raymond, Health Commissioner, Brooklyn, N Y , Major Charles Smart, Surgeon U S A , Washington, D C

II The Sanitary Conditions and Necessities of School Houses and School Life First prize, $500 , second prize, $200

The object and intention of these essays is to furnish instruction to those having the care of common schools construction of buildings, hygienic conditions, management etc , as well as valuable knowledge to teachers and parents upon matters allied to school interests

Judges —Hon Erastus Brooks, LL D , State Board of Health, New York, Dr H P Walcott, State Board of Health, Lunacy and Charity, Cambridge, Mass , Dr Granville P Conn, Pres State Board of Health, Concord, N H , Hon John Eaton, Commissioner of Education, Washington, D C , Col George E Waring, Jr , C E , Newport, R I

III Disinfection and Individual Prophylaxis against Infectious Diseases First prize, $500 , second prize, $200

This subject will embrace the kinds, value and relative merits of disinfectants, as well as the methods of use Also the means that may be employed by the individual to avoid contagious and infectious diseases

Judges —Dr S H Durgin, Health Officer, Boston, Mass , Dr J E Reeves, Secretary State Board of Health, Wheeling, W Va , Dr Gustavus Devron, Pres Aux San Ass'n, New Orleans, La , Prof Richard McSherry, M D , Baltimore, Md , Prof James L Cabell, LL D , University of Virginia, Va

IV The Preventable Causes of Disease Injury and Death in American Manufactories and Workshops, and the best Means and Appliances for Preventing and Avoiding them First prize, $500 , second prize, $200

Under this head, the conditions and necessities of the American mechanic are to be especially considered, and the thorough consideration of a class will be regarded of more value by the judges than a superficial review of the whole field Original investigations will weigh much in awarding the prizes, while compilations from existing literature or foreign statistics will not find favor with the judges

Judges —Dr E M Hunt, Secretary State Board of Health, Trenton, N J , Dr A N Bell, Editor *Sanitarian*, New York City, Major George M Sternberg, Surgeon U S A , Baltimore Md , Major John S Billings, LL D , U S A , Washington, D C , Mr W P Dunwoody, Secretary National Board of Health, Washington, D C

Conditions All essays written for the above prizes must be in the hands of the Secretary, Dr Irving A Watson, Concord, N H , on or before Oct 15, 1885 Each essay must bear a motto, and have accompanying it a securely sealed envelope containing the author's name and address, with the same motto upon the outside of the envelope A caligraphic copy of each essay will be made by the Secretary and placed in the hands of the judges, so that they will be totally ignorant as to the author

After the prize essays have been determined upon, the envelopes bearing the mottoes corresponding to the prize essays will be opened, and the awards made to the persons whose names are found within them The remaining envelopes, unless the corresponding essays are reclaimed by authors or their representatives within thirty days after publication of the awards, will be destroyed unopened by the Secretary

The judges have been selected by the American Public Health Association, the Conference of State Boards of Health, and the National Board of Health, and are empowered to reject all papers if in their opinion none are worthy of a prize The essays awarded, the prizes are to become the property of the American Public Health Association

None of the judges will be allowed to compete for a prize on the subject upon which they are to pass judgment

The judges will announce the awards in the second week of December, 1885, at the annual meeting of the American Public Health Association

It is intended that the above essays shall be essentially American in their character and application, and this will be considered by the judges as an especial merit

Competition is open to authors of any nationality, but all the papers must be in the English language

It is expected that arrangements can be made to have these essays widely distributed to the public, and to the persons mostly interested in the respective subjects in the United States The American Public Health Association earnestly appeals to those able to compete to take part in this work, which it is believed will do much to augment the health, comfort, and happiness of the people

Per order Executive Committee,
IRVING A WATSON, *Sec'y*

OFFICERS AND COMMITTEES OF THE AMERICAN PUBLIC HEALTH ASSOCIATION, ORGANIZATION, 1884–85

President, Dr James E Reeves, Wheeling, W Va , First Vice President, Hon Erastus Brooks, LL D , Richmond, N Y , Second Vice President, Dr Henry B Baker, Lansing, Mich , Secretary, Dr Irving A Watson Concord, N H , Treasurer, Dr J Berrien Lindsley, Nashville, Tenn (*Ex Officio* Members Executive Committee)

Standing Committees —Executive Committee, Elective Dr Henry P Walcott, Cambridge, Mass, Major Charles Smart, U S A, Washington, D C, Dr G B Thornton, Memphis, Tenn, Dr D W Hand, St Paul, Minn, Dr Gustavus Devron, New Orleans, La, Dr H B Horlbeck, Charleston, S C

Advisory Council —The President, *ex officio,* Alabama, Dr R D Webb, Livingston, Arkansas, Dr J A Dibrell, Little Rock, California, *Dr F W Hatch, Sacramento, Colorado, Dr Charles Ambrook, Boulder, Connecticut, Prof C A Lindsley, New Haven, Delaware, Dr L P Bush, Wilmington, Florida, Dr Robert B S Hargis, Pensacola, Georgia, Dr W H Elliott, Savannah, *Illinois, Prof Hosmer A* Johnson, Chicago, Indiana, Dr E S Elder, Indianapolis, Iowa, Dr W S Robertson, Muscatine, Kentucky, Dr Pinckney Thompson, Henderson, Louisiana, Dr S S Herrick, New Orleans, Maine, Dr C G Adams, Portland, Maryland, Prof George H Rohé, Baltimore, Massachusetts, Dr S H Durgin, Boston, Michigan, Dr Foster Pratt, Kalamazoo, Minnesota, Prof C N Hewitt, Red Wing, Mississippi, Dr Wirt Johnston, Jackson, Missouri, Dr Joseph Spiegelhalter, St Louis, New Hampshire, Dr Granville P Conn, Concord, New Jersey, *Dr* W K Newton, Paterson, New Mexico, Dr W T Parker, U S A, Ft Union, New York, Dr Jos H Raymond, Brooklyn, North Carolina, Dr Thos F Wood, Wilmington, *Ohio, Dr R Harvey* Reed, Mansfield, Pennsylvania, Crosby Gray, Esq, Pittsburgh, Rhode Island, Dr Chas H Fisher, Providence South Carolina, Dr T Grange Simons, Charleston, Tennessee, Col D P Hadden, Memphis, Texas, Dr R M Swearingen, Austin, Vermont, Hon Henry D Holton, Brattleboro', Virginia, Prof J L Cabell, University of Va, West Virginia, Dr T A Harris, Parkersburgh, Wisconsin, Dr J T Reeve, Appleton, Dist of Columbia, Maj Sam'l A Robinson, Washington, U S Army, Maj Geo M Sternberg, Baltimore, Md, U S Navy, Medical Director Albert L Gihon, Washington, D C, U S M H Serv, Surg Walter Wyman, Baltimore, Md

REPORT FROM INDIANA

BY GEORGE SUTTON, M D, AURORA, IND

Presented in the Section of State Medicine and Hygiene of American Medical Association, May, 1884

As has already been reported to the American Medical Association, the Legislature of the State of Indiana established a State Board of Health in 1881, with subordinate boards in each county, township, and city in the State As the work was new, there was some difficulty, at first, in getting the different boards of health in good working order, but as the officers and physicians become accustomed to their duties, the work becomes more efficient, and in reporting progress at the present time, we can say that last year, reports were received from every county in the State, with the exception of two, and a large amount of valuable statistical matter has been collected The statistics, however, are yet imperfect, and must necessarily be so until not only every county, but every township physician and midwife in the State is heard from We feel in hopes, however, as the work is now progressing favorably, that we shall soon be able to approximate accuracy, and present to the profession statistical matter of the utmost value

Much has yet to be done in the State of Indiana by State and county legislation to meet the wants of the people We require more convenient and better hospital accommodations Most counties have what is called the Poor House, a department of which is assigned for the accommodation of the sick The Poor House is generally situated upon a farm, and in many instances at a remote distance from the principal towns and cities in the county As an instance, we give Dearborn county, which will represent the condition of many other counties in the State, this county contains upwards of 30,000 inhabitants In the county there are Lawrenceburgh, Hardingtown, Aurora, Cochran and Wilmington, towns and villages all within a few miles of each other Our Poor House, however, with accommodations for the sick, is on a farm at a remote distance, between eight and ten miles from the nearest town and several miles from the nearest physician, and in wet weather when the roads are muddy is almost inaccessible As it is from the towns and cities that three-fourths of the paupers are sent to the hospital, efforts have been repeatedly made by the Dearborn County Medical Society to procure a change, and have a hospital where it would be more accessible To show the necessity of this change, only a few weeks since a patient who had been sick with typhoid fever about twenty days, was sent by the township trustees of Washington township nearly fifteen miles over rough roads to the Poor House, the consequence was that he died the next day The attending physician at the Poor House, Dr Kyle, has given me a note which speaks for itself

---

* Deceased

The subject several years ago was regarded of so much importance that we presented to the County Medical Society a series of resolutions, which were unanimously adopted, and a committee of physicians appointed to confer with the County Commissioners These resolutions in a few words express what we believe to be the wants of many counties in the State In the preamble it is stated that the members of the County Medical Society believe that they understand and know the wants of the county in relation to the sick better than any other class of our citizens, and consequently they consider it their duty to present to the Commissioners what is needed They state in these resolutions that as the great object of a hospital is the restoration of patients to health, it should be not only in a healthy location, but easily accessible to that portion of the country that furnishes the largest number of patients That Lawrenceburgh and Aurora, cities situated near each other and rapidly increasing in population, do furnish more than three-fourths of the patients, and certainly require at the present time a hospital that will be convenient to each city

That these cities are now large enough to require a hospital easily accessible, each city should have a light ambulance wagon kept under the control of the township trustee for the easy removal of the sick, or those who have received severe injuries or require public aid, to the hospital

That the County Hospital should be under the control of an intelligent physician, or physicians, who may be easily procured in cases of emergency,—this, we know, would always be the case if the hospital was situated near the cities of Aurora and Lawrenceburgh, or our large cities

That in cases of railroad or steamboat accidents, or accidents occurring at the mills, foundries or machine shops in our cities, when a number of persons are injured, we want a hospital easily accessible, where patients can immediately receive the proper medical and surgical treatment

That this hospital may be made the proper place for the treatment of dypsomania, where patients may be kept under the management of an intelligent physician until self control or the will power is restored

That Dearborn county, and other counties, not only require a change at the present time in their hospital accommodations, but also the erection of pest houses, separate from the hospital for the protection of our citizens from the spread of contagious and infectious diseases, such as small-pox, typhus fever and other infectious diseases

Had a patient from the South, unwell with the incipient stages of yellow fever during the epidemic, been landed within our county from a railroad car, or a steamboat ascending the river from the South, it is almost impossible to estimate the consequences from the loss of life, and loss to our citizens in a business point of view, that possibly might have occurred from the spread of the infection [Without taking into consideration the loss of life, it has been estimated that in the year 1878, more than 160,000,000 of dollars was lost to the inhabitants of the Mississippi Valley, below the mouth of the Ohio river, by the prevalence of the yellow fever] We know that from the introduction and spread of this disease near Gallipolis, the inhabitants of the Ohio Valley may, under certain circumstances, suffer the fatal and depressing consequences of this pestilence A committee was appointed to confer with the County Commissioners, but as a farm had been purchased, the Commissioners were not disposed to make any change We present these views to show what we believe to be absolutely needed in our State —a change in our hospital accommodation

STATE HOSPITAL

There will probably be an effort made at the next meeting of the Indiana State Medical Society to procure, through the Legislature, the erection of a large State Hospital at Indianapolis, for the treatment of the sick Although such a hospital would be of local benefit, and might be of benefit in the treatment of chronic diseases, it must be obvious that most of the cases requiring medical treatment cannot be transported safely from distant and different parts of the State It would certainly be impracticable to transport patients laboring under acute diseases a very great distance, many of whom would die before they could be got to the hospital, or those suffering from contagious or infectious diseases, the removal of whom would endanger the public, or those surgical cases arising from accidents requiring immediate treatment, such as the reduction of dislocations, replacing of fractures, and dressing of wounds, etc , etc , all of which might be removed a short distance to a county hospital, therefore, at the present time we consider that it is an improvement in our local county hospitals that is most needed in Indiana

TO REGULATE THE PRACTICE OF MEDICINE

For several years the subject of State legislation in reference to the practice of medicine in Indiana has been brought before the State Medical Society Committees have been appointed, bills have been drafted, but nothing has yet been accomplished except the agitation and discussion of the subject As it would be impossible at the present time to procure the passage of a bill by our Legislature, that would exclude all from the practice of medicine except the regular well educated physician, a portion of the members of our State Medical Society have been in favor of a bill that would exclude hereafter all from the practice of medicine except those who have received diplomas from the schools or colleges of their respective systems of medicine They would place all the different systems of medicine upon the same equality in the eye of the law for the purpose of preventing persons from practicing medicine in the regular profession without being properly qualified Others again, regarding the regular system of medicine as the only true system, being founded upon the accumulated experience of 2,000 years, consider that the object of the law should be to protect the public against that which they believe to be wrong, such as that which our Code of Ethics regards as errors, delusions, or false systems of medicine, and which does not allow the members of the regular profession to even consult with members of those systems, or in any way recognize them as members of the medical profession They consider that the State Medical Society, composed of regular physicians, would be acting inconsistently to ask the Legislature through their committee to pass a law by which all the different systems and delusions in medicine would be put upon the same equality with the regular profession

The difference of opinion upon this subject has been one of the principal difficulties in procuring a law to regulate the practice of medicine in Indiana, and we would certainly like to hear gentlemen express their opinion whether, as regular physicians, we can consistently go before the Legislature and ask for a law that will protect that which we believe to be wrong—that which we believe erroneous, and that which we believe to be false, for the purpose of preventing individuals who are not properly qualified from practicing in our own system of medicine Is it not asking to legalize one evil to prevent another?

DISEASED MEAT

Another subject that requires legislation in our State, is the passage of a law to more effectually protect the public against the sale in our markets of diseased meat We know at the present time that there is a desire to suppress facts in relation to the existence of trichina in our pork, but after an experience of ten years, in which I have examined a large amount of pork, I can say that from 3 to 16 per cent of the hogs in South-eastern Indiana are infected with this parasite The prevalence of the disease amongst the hogs varies greatly in different localities I know that in one instance pork that was brought to my office by a farmer for examination was found to be filled with trichina This pork, instead of being used in his family, we have the most conclusive evidence was at once shipped to Cincinnati, and sold in the market A few years ago I presented a report to the Indiana State Medical Society, in which I collected some facts Drs Harding and Robbins, of Lawrenceburgh, informed me that they had microscopically examined specimens from 245 different hogs slaughtered in the vicinity of Lawrenceburgh, and found trichina present in 40 of the specimens, making about 16⅓ per cent of all examined Drs Gatch and Miller, of Lawrenceburgh, also informed me that they had examined with a microscope 200 hogs killed for pork, and found trichina in 13, making about 6 per cent Dr G V Stevenson, of Rising Sun, also wrote to me that he had found trichina in pork killed in Ohio county, and Dr Sale, of Dillsborough, told me that he found trichina in pork killed in that section of country

We have seen notices recently in the newspapers that trichina had been discovered, and that trichinosis had prevailed at Liberty, South Bend, Fort Wayne, Decatur, and other places in Indiana, and it is more than probable that many cases of sickness which are diagnosed as typhoid fever, chronic diarrhœa, etc , are produced from trichina

When we bear in mind that upwards of 5,000,000 of hogs are slaughtered and packed in the Western States, not including those which are put up for family use by the farmers, that if 4 per cent of this pork is diseased, which we believe to be a low estimate, we have 221,484 diseased hogs put annually upon the market, or, at an average of 200 pounds to the hog, 44,296,800 pounds of diseased meat, every ounce of which, under favorable circumstances, is capable of producing disease

From these facts we think, as this disease prevails in our State to a considerable extent, that a law should be passed in the State of Indiana to prohibit the sale of pork in our markets unless it bears the stamp of having been examined by a properly authorized meat inspector and found free from disease

FOREIGN CORRESPONDENCE

BERLIN LETTER.

BERLIN, Jan 28, 1885

At a meeting of the Physiological Society, the Director of the chemical laboratory of the Physiological Institute, stated that he had discovered a new element in the pancreatic juice which he called *Adenin* It belongs to the same group as guanine and exanthine Its chemical formula is $C_5 H_5 N_5$ He utilized 42 litres of a watery pancreatic extract in finding it With water of hydration it forms long, needle form crystals It dehydrates when exposed to the atmosphere With the various acids it forms salts

A CASE OF OVARIOTOMY IN A PATIENT WITH HYSTERICAL HEMIANÆSTHESIA

I am indebted to Dr L Landau for the details of this most interesting case I had the pleasure of seeing the patient at his office a few days ago, and could personally verify the points of the paper published by himself and Dr E Remak on this subject (*Zeitsch fur Klin Med Bd*, VI H 5)

The patient's father died of brain disease She herself was in good health up to 15 years old, when she was wounded on the right half of the forehead by a blow from a stone In the same year she fell into the water, which brought on an attack of pneumonia, since which time she has often spit blood Menstruation appeared at 18, remained irregular for a year, and ceased altogether at 46 After a second attack of inflammation of the lungs, at 20 years of age, she had pain in the groin, paralysis and anæsthesia in the left leg, so that she could neither walk nor stand At that time Von Mitscherlich made out a painful swelling in the left groin This he treated antiphlogistically, and the paralysis of the left leg with the induced current, which enabled her to go about with two crutches At 29 years of age she came to R Remak, having for nine years suffered with anomalous pains, such as a bending of the outstretched tongue to the right, obstinate aphonia, an attack of dyspnœa, serious emesis, painful cough, the Poor House, Dr Kyle, has given me a note which speaks for itself

The subject several years ago was regarded of so much importance that we presented to the County Medical Society a series of resolutions, which were unanimously adopted, and a committee of physicians appointed to confer with the County Commissioners These resolutions in a few words express what we believe to be the wants of many counties in the State In the preamble it is stated that the members of the County Medical Society believe that they understand and know the wants of the county in relation to the sick better than any other class of our citizens, and consequently they consider it their duty to present to the Commissioners what is needed They state in these resolutions that as the great object of a hospital is the restoration of patients to health, it should be not only in a healthy location, but easily accessible to that portion of the country that furnishes the largest number of patients That Lawrenceburgh and Aurora, cities situated near each other and rapidly increasing in population, do furnish more than three-fourths of the patients, and certainly require at the present time a hospital that will be convenient to each city

That these cities are now large enough to require a hospital easily accessible, each city should have a light ambulance wagon kept under the control of the township trustee for the easy removal of the sick, or those who have received severe injuries or require public aid, to the hospital

That the County Hospital should be under the control of an intelligent physician, or physicians, who may be easily procured in cases of emergency,—this, we know, would always be the case if the hospital was situated near the cities of Aurora and Lawrenceburgh, or our large cities

That in cases of railroad or steamboat accidents, or accidents occurring at the mills, foundries or machine shops in our cities, when a number of persons are injured, we want a hospital easily accessible, where patients can immediately receive the proper medical and surgical treatment

That this hospital may be made the proper place for the treatment of dypsomania, where patients may be kept under the management of an intelligent physician until self control or the will power is restored

That Dearborn county, and other counties, not only require a change at the present time in their hospital accommodations, but also the erection of pest houses, separate from the hospital for the protection of our citizens from the spread of contagious and infectious diseases, such as small-pox, typhus fever and other infectious diseases

Had a patient from the South, unwell with the incipient stages of yellow fever during the epidemic, been landed within our county from a railroad car, or a steamboat ascending the river from the South, it is almost impossible to estimate the consequences from the loss of life, and loss to our citizens in a business point of view, that possibly might have occurred from the spread of the infection [Without taking into consideration the loss of life, it has been estimated that in the year 1878, more than 160,000,000 of dollars was lost to the inhabitants of the Mississippi Valley, below the mouth of the Ohio river, by the prevalence of the yellow fever] We know that from the introduction and spread of this disease near Gallipolis, the inhabitants of the Ohio Valley may, under certain circumstances, suffer the fatal and depressing consequences of this pestilence A committee was appointed to confer with the County Commissioners, but as a farm had been purchased, the Commissioners were not disposed to make any change We present these views to show what we believe to be absolutely needed in our State —a change in our hospital accommodation

STATE HOSPITAL

There will probably be an effort made at the next meeting of the Indiana State Medical Society to procure, through the Legislature, the erection of a large State Hospital at Indianapolis, for the treatment of the sick Although such a hospital would be of local benefit, and might be of benefit in the treatment of chronic diseases, it must be obvious that most of the cases requiring medical treatment cannot be transported safely from distant and different parts of the State It would certainly be impracticable to transport patients laboring under acute diseases a very great distance, many of whom would die before they could be got to the hospital, or those suffering from contagious or infectious diseases, the removal of whom would endanger the public, or those surgical cases arising from accidents requiring immediate treatment, such as the reduction of dislocations, replacing of fractures, and dressing of wounds, etc , etc , all of which might be removed a short distance to a county hospital, therefore, at the present time we consider that it is an improvement in our local county hospitals that is most needed in Indiana

TO REGULATE THE PRACTICE OF MEDICINE

For several years the subject of State legislation in reference to the practice of medicine in Indiana has been brought before the State Medical Society Committees have been appointed, bills have been drafted, but nothing has yet been accomplished except the agitation and discussion of the subject As it would be impossible at the present time to procure the passage of a bill by our Legislature, that would exclude all from the practice of medicine except the regular well educated physician, a portion of the members of our State Medical Society have been in favor of a bill that would exclude hereafter all from the practice of medicine except those who have received diplomas from the schools or colleges of their respective systems of medicine They would place all the different systems of medicine upon the same equality in the eye of the law for the purpose of preventing persons from practicing medicine in the regular profession without being properly qualified Others again, regarding the regular system of medicine as the only true system, being founded upon the accumulated experience of 2,000 years, consider that the object of the law should be to protect the public against that which they believe to be wrong, such as that which our Code of Ethics regards as errors, delusions, or false systems of medicine, and which does not allow the members of the regular profession to even consult with members of those systems, or in any way recognize them as members of the medical profession. They consider that the State Medical Society, composed of regular physicians, would be acting inconsistently to ask the Legislature through their committee to pass a law by which all the different systems and delusions in medicine would be put upon the same equality with the regular profession.

The difference of opinion upon this subject has been one of the principal difficulties in procuring a law to regulate the practice of medicine in Indiana, and we would certainly like to hear gentlemen express their opinion whether, as regular physicians, we can consistently go before the Legislature and ask for a law that will protect that which we believe to be wrong—that which we believe erroneous, and that which we believe to be false, for the purpose of preventing individuals who are not properly qualified from practicing in our own system of medicine. Is it not asking to legalize one evil to prevent another?

DISEASED MEAT.

Another subject that requires legislation in our State, is the passage of a law to more effectually protect the public against the sale in our markets of diseased meat. We know at the present time that there is a desire to suppress facts in relation to the existence of trichina in our pork, but after an experience of ten years, in which I have examined a large amount of pork, I can say that from 3 to 16 per cent of the hogs in South-eastern Indiana are infected with this parasite. The prevalence of the disease amongst the hogs varies greatly in different localities. I know that in one instance pork that was brought to my office by a farmer for examination was found to be filled with trichina. This pork, instead of being used in his family, we have the most conclusive evidence was at once shipped to Cincinnati, and sold in the market. A few years ago I presented a report to the Indiana State Medical Society, in which I collected some facts. Drs. Harding and Robbins, of Lawrenceburgh, informed me that they had microscopically examined specimens from 245 different hogs slaughtered in the vicinity of Lawrenceburgh, and found trichina present in 40 of the specimens, making about 16⅓ per cent of all examined. Drs. Gatch and Miller, of Lawrenceburgh, also informed me that they had examined with a microscope 200 hogs killed for pork, and found trichina in 13, making about 6 per cent. Dr. G. V. Stevenson, of Rising Sun, also wrote to me that he had found trichina in pork killed in Ohio county, and Dr. Sale, of Dillsborough, told me that he found trichina in pork killed in that section of country.

We have seen notices recently in the newspapers that trichina had been discovered, and that trichinosis had prevailed at Liberty, South Bend, Fort Wayne, Decatur, and other places in Indiana, and it more than probable that many cases of sickness h are diagnosed as typhoid fever, chronic diar- etc., are produced from trichina.

'n we bear in mind that upwards of 5,000,000 of hogs are slaughtered and packed in the Western States, not including those which are put up for family use by the farmers, that if 4 per cent of this pork is diseased, which we believe to be a low estimate, we have 221,484 diseased hogs put annually upon the market, or, at an average of 200 pounds to the hog, 44,296,800 pounds of diseased meat, every ounce of which, under favorable circumstances, is capable of producing disease.

FOREIGN CORRESPONDENCE.

BERLIN LETTER.

BERLIN, Jan. 28, 1885.

At a meeting of the Physiological Society, the Director of the chemical laboratory of the Physiological Institute, stated that he had discovered a new element in the pancreatic juice which he called *Adenin*. It belongs to the same group as guanine and exanthine. Its chemical formula is $C_5H_5N_5$. He utilized 42 litres of a watery pancreatic extract in finding it. With water of hydration it forms long, needle form crystals. It dehydrates when exposed to the atmosphere. With the various acids it forms salts.

A CASE OF OVARIOTOMY IN A PATIENT WITH HYSTERICAL HEMIANÆSTHESIA.

I am indebted to Dr. L. Landau for the details of this most interesting case. I had the pleasure of seeing the patient at his office a few days ago, and could personally verify the points of the paper published by himself and Dr. E. Remak on this subject (*Zeitsch. für Klin. Med. Bd.*, VI. H. 5).

The patient's father died of brain disease. She herself was in good health up to 15 years old, when she was wounded on the right half of the forehead by a blow from a stone. In the same year she fell into the water, which brought on an attack of pneumonia, since which time she has often spit blood. Menstruation appeared at 18, remained irregular for a year, and ceased altogether at 46. After a second attack of inflammation of the lungs, at 20 years of age, she had pain in the groin, paralysis and anæsthesia in the left leg, so that she could neither walk nor stand. At that time Von Mitscherlich made out a painful swelling in the left groin. This he treated antiphlogistically, and the paralysis of the left leg with the induced current, which enabled her to go about with two crutches. At 29 years of age she came to R. Remak, having for nine years suffered with anomalous pains, such as a bending of the outstretched tongue to the right, obstinate aphonia, an attack of dyspnœa, serious emesis, painful cough, sometimes cramps all over the body The severity of the general pains and the intensity of the pain in the groin swelling, were coincident and equal in degree At 28 years, after much pain she had an attack of paralysis of the left arm, which R Remak attributed to neuritis, and treated this as well as the other symptoms with the galvanic current In January, 1860, Dr E Martin, after making a digital examination, made out a fluctuating tumor in the left iliac fossa, which he diagnosed as an ovarian tumor of the left side After the examination she was seized with much pain and vomiting After applications of the galvanic current to the groins and back, the patient had no more vomiting or dyspnœa, mobility and sensibility returned to the left leg, and she was able to walk, first with one crutch, then without any crutch, and could even stand alone for a short time upon the left foot In May, 1862, she was suddenly seized with photophobia and blepharospasmus duplex, which A V Graefe diagnosed on the spot as pressure on the fifth pair of nerves, and of the zygomatico-temporal nerves Remak believed all of her troubles started from some derangement of the sympathetic, and diagnosed *hysteria* P Guttmann, writing in 1865 about this same woman traced her nervous troubles to the cicatrix on the left side of the forehead She was daily at Griesinger's clinic for nervous diseases, at Charite, from 1865 to 1868, and he diagnosed hysteria with exaltation In 1867 the cicatrix was excised, as the patient had much pain in that region, and in 1868 the right supra-orbital nerve was resected, after which the general cramps disappeared and never came back, and sensibility of the right half of the body returned From 1868 to 1882 the patient was not in any hospital, and was able to work somewhat with her hands As the woman came under our notice she had complete aphonia (laryngoscopic examination showed deficient closing and tension of the vocal cords during phonation), subjective dyspnœa, with rapid respiration, (fifty per minute), no objective signs in the heart or lungs, pain in the groin swelling, and therefrom the sickness and nausea seemed to extend to the stomach and throat Here it may be remarked that the galvanic current from the tumor to the legs relieved the symptoms, so that the interesting observation was made that after the spontaneous pains and the pain upon pressure over the ovarian swelling to a certain extent got better, analogous pains and symptoms set in on the right side of the belly, with spreading aura and vomiting This lasted for a short time, and then everything returned to the primary condition On the entire left side of the body to the middle line there is loss of sensibility (subjective and objective), on the right side it is normal The left side is not appreciative of strong electrical currents, of the puncture of a pin, of heat or cold, or of sticking a needle well into the flesh This *hemanæsthesia sinistra* extends to the middle line of the mucous membrane of the nose, mouth, tongue, vagina, etc The sense of taste and the sense of smell on the left side are absent, but the patient *hears* better with the *left* ear than with the *right* (right ear, watch at 39 ctm, left ear 105 ctm), and sees better with the *left* eye than with the *right* (right 4 200, left 9 200) The left conjunctiva is anæsthetic Frequent examinations with the galvanic and Faradic currents made no change in the hemianæsthesia Metalloscopy, magnetoscopy and examinations under an anæsthetic and with static electricity made no change From this one might conclude, with M Rosenthal, that it was a case of hemianæsthetic torpor of one half of the brain With the application of the galvanic current to the right side of the head, using a diminishing current, flashes of light appeared in right eye, and giddiness was apparent when the current was passed through the brain, but no acoustic symptoms were developed In passing a current of ten milliamperes through the left half of the brain there was not the slightest trace of giddiness and no flashes in left eye Some motor troubles in the neighborhood of the cerebral nerves may be noticed Slight ptosis on both sides, partial paralysis and oculo motor disorders and atypical double sight, diminution of distance in field of vision The patient wears a glass with a dim blue glass on left eye to correct the diplopia When the mouth is opened the left corner is drawn down, but there is no well defined facial paralysis The uvula points strongly to the left, while the velum moves regularly up and down The tongue points to the left, and moves in a circle from left to right, which both R Remak and P Guttmann have said surpasses anything in their experience in point of rarity and interest There is no disturbance of speech or deglutition The leg on the left side is 1 to 1 5 ctm smaller than on the right side, and is somewhat colder Motor weakness is plainly observable There is no rigidity Tendon reflex is alike on both sides, the foot reflex is not seen The gait of the patient is very strange and has no resemblance to ordinary hemiplegia While she cannot move a step without a crutch, with the left shoulder braced up, she walks along rapidly, bringing the right leg around in a circle in a long sweep, and simulating with the crutch the movements of the left leg, which hangs helplessly at the side With her eyes shut she cannot move the left foot, but with eyes open she can use the left paralytic hand for little things, even though not controlled by the eyes On October 15, 1882, a large dermoid cyst was removed by laparotomy The results were negative Patient complained greatly of pain in the index and middle fingers of the left hand The movement and anæsthesia of the left leg became worse, and she complained greatly of pain in the left groin Three months after the operation, pressure over the right ovary, or bimanual pressure over the stomach or liver occasions no pain but the moment that pressure is made over the left ovarian region the patient is thrown into great pain and semi-convulsions, and not only this region, but the whole left half of the belly The loins under the musculus quadratus lumborum, over the crista ossis ilei, and the os descendeus pubis, over the left half of the pudenda, is anæsthetic, and with pain irradiating from a center upon pressure In November, 1882, the patient went to the hospital at Moabit Large blisters were applied over the left hypogastrium It was interesting to notice that, although a pin might be run through the flesh without pain, yet within the blister the least touch produced the greatest agony. I saw the patient on January 23, 1885. She came into Dr. Landau's office leaning upon a crutch, and wheezing like a person with an attack of asthma. Her respiration was rapid and shallow, her speech jerky, and there was well-marked aphonia. When she tried to speak she brought on a severe fit of coughing. Pressure over the left ovarian region was attended with no symptoms whatever. Pressure over the right ovary set up a modified convulsive spasm, and the patient complained of much pain, although Dr. Landau said that the ovary was gradually becoming less sensitive. *Pressure over the liver* was attended with great pain and muscular contortion. This feature is of recent origin. There is an absolute anæsthesia of the left half of the body, including the mucous membranes on that side. A needle was pushed through the flesh of the leg and arm, of the stomach and chest, and into the nipple, without any sign of pain. The conjunctiva, the mucous membrane of nose, mouth, and vagina were all equally anæsthetic up to the median line. The hemianæsthesia is absolute and complete. Sense of smell and of taste on left side of nose and tongue are *nil*. Take it for all in all, this case, which has engaged the attention of physicians and poli-kliniks in Berlin for many years, is as interesting in all its particulars as any one that I know of.

H. R. B.

DOMESTIC CORRESPONDENCE.

PITTSBURGH, PA.

EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Dear Sir:—You spring the question in your editorial of the JOURNAL of Feb. 7, 1885, Is tolerance of unusually large doses in any acute disease during its progress evidence that the remedy is indicated or acting favorably? Now this question is of interest to the medical profession at large, and as we can come to no conclusion except through facts and observations gathered at the bedside by the general profession, I take this opportunity to direct your attention to a few acute diseases, the treatment of which will prove conclusively the affirmative of your interrogation. It is well known to those who have treated yellow fever that there is a great tolerance and even demand on the part of the patient suffering from this disease for calomel and quinine, in large doses, and I can truthfully testify that these were *the* remedies I depended on the most in carrying my patient safely through the disease. Quinine and calomel, in large doses, were indeed the sheet anchors in this disease. It is well known by those who have treated malarial congestive chills, or the so-called pernicious fever, how much the patient's life depends on large doses of quinine at stated intervals just after the reaction from the first chill.

Now let us examine the effect of alcohol in diphtheria. It has been broached, if not asserted, that alcohol acts as a micrococci-cide. If it be true that alcohol is a killer of these germs which are claimed to be the cause of diphtheria, then if there be great tolerance on the part of the patient to alcohol why not administer it? Alcohol no doubt is an antiseptic in diphtheria, we know it is a stimulant. If it acts beneficially in either of these three ways it must do good. About two weeks ago my attention was called to the amount of whisky that was administered to four children in the same family suffering with diphtheria. The four consumed during their sickness two quarts of whisky and all recovered—without any apparent bad results. Of course it is difficult to judge in the treatment of disease as to whether the drug administered formed a curative power or whether our patient recovered in spite of it, but it seems as evident to my mind as anything in medicine that alcohol in the treatment of diphtheria does the patient no harm but a great deal of good.

There is another point in your editorial which I wish to notice, and that is in regard to 20 per cent. of mortality in treatment of diphtheria as being a high ratio of deaths. But when it is known that the so-called pseudo-membranous croup and cases that neglected to call me in at the incipiency of the disease are all included in this death rate, the ratio is not so high. I have noticed that when I have been called in to treat a case of diphtheria at the incipiency of the disease my success has been remarkably good.

Yours respectfully, J. M. BATTEN.

NEW YORK LETTER.

NEW YORK, Feb. 14, 1885.

The recent meeting of the State Medical Society at Albany was noteworthy on account of the almost complete absence of National Code men from its sessions. The principal matter of interest occurring at it was the discussion of a proposed State Board of Medical Examiners for the purpose of granting licences to practice (this power being taken from the colleges), and the recommendation of a bill providing for the organization of such a board, to be introduced into the Legislature.

The bill thus agreed upon fixes the number of examiners at nine, who are to be appointed by the regents of the University of the State of New York, as follows: Six from the members of the State Medical Society (of whom three are to be elected from those not connected with incorporated medical colleges, and three from those who are members of the faculties of such colleges), and the remaining three from the other two incorporated medical societies of the State in proportion to their representation, viz.: two from the Homœopathic, and one from the Eclectic State Society. They are to be appointed annually, but are eligible for reappointment. The pay of the examiners is to be $800, and the following subjects are to be included in the examination: Anatomy, histology, physiology, hygiene, chemistry, pathology, principles and practice of medicine, surgery, midwifery and therapeutics. The following is the method of examination prescribed:

"All such examinations shall be conducted in writing or orally, at the option of the board, * * * * provided that each applicant, upon receiving from the said regents an order for examination, shall also receive a confidential number, or mark, which he or she shall place upon his or her examination papers in lieu of signature, so that when said papers are passed upon by the examiner the latter shall not know by what applicant said papers were prepared, that, upon each day of examination, all candidates shall be given the same set or sets of questions, that the examinations upon the principles and practice of medicine shall only be held after the other examinations have been made and their results recorded, that, upon these two subjects, three sets of questions, prepared by the representatives in said board of the Medical Society of the State of New York, the Homœopathic Medical Society of the State of New York and the Eclectic Medical Society of the State of New York, respectively, shall be given to each applicant, and the applicant shall elect which one of the said sets of questions he or she shall answer, and that the merit of these answers shall be exclusively passed upon by those members of the board by whom the questions were prepared ''

At the present time the bill has not as yet been presented to the Legislature, as the Committee on Legislation was instructed to first have it carefully revised throughout under competent legal advice

In the meanwhile, another bill (similar to the one discussed last year) providing for a State Board of Examiners on which the regular profession, the homœopathists and the eclectics are equally represented, that was introduced first upon the meeting of the State Medical Society, has received one reading in the Assembly There seems to be little likelihood, however, of either bill passing, as the whole body of the regular profession, both old and new code, is opposed to the latter on account of its giving an equal representation with itself to each branch of irregulars, and the homœopathists and eclectics are opposed to the first because it allows them such a small representation Notwithstanding the fact that this bill received the unanimous endorsement of the State Society, a large portion of the regular profession are urgently opposed to the formation of any Board of Examiners which has any representation whatever from the irregulars upon it It would certainly be a strange spectacle to see the representatives of the New York County Medical Society, to which all the New York members of the State Society belong, sitting on the same board with one or more representatives of the Eclectic College, which for a considerable number of years it has been endeavoring to permanently deprive of its charter—in which laudable undertaking it has already expended many hundreds of dollars, and is still more or less actively engaged

Some of the druggists in this city are now on the anxious bench, as an investigation into the purity of their wares has been commenced under the direction of Dr Cyrus Edson, of the health department, and forty samples of quinine, purchased from different shops through individuals who were not suspected of doing it for this purpose, are at present undergoing analysis One arrest has already been made, and more are likely to follow The druggist arrested was charged at the police court with violating section 16 of the Sanitary Code, by selling to an officer attached to the second division of the Sanitary Bureau ten powders of alleged sulphate of quinine, of ten grains each, which were adulterated with a large quantity of milk sugar He was admitted to bail, and the trial has not yet come off

The value of taking advantage of special opportunities as they may arise from time to time in life, is strikingly illustrated in the professional career of the late Dr James Owens Smith, who died January 30 At the time that he was graduated from the College of Physicians and Surgeons, in 1825, the Republic of Columbia, then recently established under the presidency of Simon Bolivar, had just purchased in the United States a frigate which was about to sail for Venezuela, and for which a surgeon was needed On account of the high character of his recommendations, Dr Smith secured the appointment, although there were a large number of other applicants for the position, and the frigate sailed at once to Caracas where, as it so happened, there was a violent epidemic of yellow fever Some of the local physicians having died and others deserted their post of duty there was an instant demand from the inhabitants for the services of the ship's surgeon, and he entered upon the work before him with determination and energy Having brought the disease under control by the enforcement of sanitary measures, he was sent for by the inhabitants of a neighboring city where the fever was raging, and here also his labors were crowned with success Sir Robert Ker Porter, the British Consul at Caracas, now appointed him his physician, and took him into his household, and for five years he had an extensive practice in Venezuela He then returned to New York and, curiously enough, shortly after his arrival, in 1832, the first epidemic of cholera occurred in that city His former experience in the yellow fever outbreaks now stood him in good stead, and so highly were his services appreciated, that he at once obtained a large practice, which he retained for forty years, when he retired from active work

Gaillard's Medical Journal is to be maintained, and the future editor is to be Dr P Brynberg Porter, who will have for his collaborators Drs T Gaillard Thomas, and George T Harrison, of New York, Hunter McGuire, of Richmond, Va , and S M Martin, of Mobile, Ala P B P

NECROLOGY

IN MEMORIAM

James Gray Thomas, M D , was born near Bloomfield, Kentucky, June 24th, 1835

He began his medical studies in Louisville, Kentucky, in the school in which the late Samuel D Gross, M D , LL D , then taught

He graduated in medicine from the University the City of New York in 1856, and began his work in Bloomfield, the place of his birth and early home He subsequently settled near Sardis, Mississippi, where he was in general practice when the late war broke out He entered the Confederate service as a surgeon and continued in that capacity till the war closed

He married in Savannah November 16th, 1865, and made that city the place of his residence

He served in the Legislature of Georgia through the sessions of 1875 and 1876 This apparent divergence from the line of his chosen vocation, was made by him in obedience to a sense of public duty and in compliance with the urgent solicitation of eminent citizens who desired to return to the Legislature a judicious and public-spirited medical man, who would lead in procuring the enactment of laws relating to the interests of hygiene in the State In accepting such public trusts he was especially moved by the hope that he might help to obtain for the State an effective Health Board During the session of 1875, the first of his service, the Legislature passed "an act to create a State Board of Health for the protection of life and health, and to prevent the spread of disease in the State of Georgia, and for other purposes" He took a most important part in the preparation and passage of this measure The Board thus created, consisted of nine physicians, together with the Comptroller General and Attorney-General and State Geologist, and it chose Dr Thomas as its first President, his name appearing as such in its printed reports for the years 1875 and 1876 He was diligent in his attention to the work of the Board and endeavored faithfully to make its ministrations effective for the good of the commonwealth For the first time in the history of the State "physicians were recognized as an active and working element in its government" Systematic efforts were made throughout the State to increase the number of those who would favor sanitary reform, to establishing a correct method of obtaining and using vital statistics, to organize local boards of health, to define the powers of such boards, and to defend the people on the coast-line and over avenues of traffic with the interior, against the incursions of pestilence from abroad, and to teach them to recognize and fight against preventable diseases within their own borders A due supervision of all the public charities of the State was also to be provided for In fact, a great movement was started which was intended to secure for the State the inestimable blessing of a good body of health-laws, wisely administered In all this admirable work Dr Thomas was justly prominent, and, had he and his associates been sufficiently sustained by legislative grants and appreciative public opinion, greater results would have been immediately realized

The good he did in turning away somewhat from the cherished and most congenial occupation of private practice to serve in public life, will link his name as that of a benefactor with the sanitary history of his State and with the annals of State medicine throughout our entire land

In 1877 "an act was passed by his State Legislature to provide for the drainage of Chatham county, so as to protect the State from epidemics of yellow fever and other diseases, and to appropriate for said purposes one-third of the State-tax of said county for the year 1877, and appointing five commissioners to carry the law into effect" On the organization of the Commissioners, March 7th, 1877, Dr Thomas was elected their chairman He took an active and zealous part in the work of the Commission, and was its chairman at the time of his death "The work done by this commission has been effective not only in promoting the public health and material prosperity of the chief commercial ocean gateway of the State, but also in contributing to arrest wholly any invasion of yellow fever since 1876"

"In the winter of 1881, Dr Thomas had strongly urged the importance of organizing in Savannah, a Citizen's Sanitary Association looking to the improvement of the public health through the united efforts of private citizens, and as auxiliary to established public methods of sanitation The result was a public meeting held in the 'Long Room' of the exchange, Dec 14th, 1881, largely attended by leading citizens of Savannah By special invitation the meeting was addressed by Dr Thomas His views were so warmly adopted that the organization of the proposed association was immediately authorized and carried into effect, Feb 10th, 1882 On this occasion he was elected President of the Association, which began with an enrollment of 259 members, subsequently largely increased Dr Thomas continued in this office to the time of his death"

Thus, while the Doctor was assiduous in the private practice of his calling, and never neglectful of its solemn obligations, he was always concerned about the welfare of the public and ready in suggesting judicious plans to enlist public-spirited citizens in measures for the general health He was rarely absent from his work, and only for brief periods of rest, when those for whose health he felt a deep sense of responsibility were least liable to be exposed to epidemic influences He was an esteemed member of the American Health Association, and no one who had the privilege of attending the session of that body in Savannah, will forget how much the success of the meeting turned on his unostentatious but effective services, and how freely and courteously the hospitalities of his delightful home were dispensed

His interest in the National Board of Health was early, consistent and continuous, and he did what he could to advocate the doctrine of the necessity of the establishment and maintenance of that body as the most ready, effective agency through which to give the entire country the benefit of adequate sanitary supervision and police, to lessen the ravages of indigenous, preventable diseases, and to prevent the introduction on the coast-line of such as threatened to invade the country from without

He was ever willing to do the work that pressed upon him to be done, and to turn aside even from the most congenial occupations of home life and the routine of his daily practice, if only the claim were addressed to his keen sense of public duty He was not only a physician, he was also a patriot It was in obedience to such motives that he left Savannah at the close of November last, although not feeling well to attend a meeting in the city of Washington to complete the arrangements for the International Medical Congress to be held in that city in the year 1887.

He was taken ill on the railway train near Richmond, but continued on to his destination. After reaching Washington his malady took the form of pneumonia. His good wife was sent for; his sympathetic medical brethren aided her in her affectionate and devoted ministrations. At one time the disease seemed to be checked, but the arrest was only simulated; he grew weaker, and on the morning of Saturday, December 6, 1884, he departed this life, following, as we have credible evidence, those who have endeavored to imitate the Good Physician.

Even this brief narrative of the life of an exalted member of the medical profession would be very incomplete if we did not record one or two more allusions to the quality of the work that he did day by day for the patients who leaned upon him for sympathy and treatment.

He was always on the alert to learn anything which might be for the advancement of his science and art. He was ready to seize a new idea, to develop and utilize it. He was studious and meditative in the line of his calling, notwithstanding the activity of his life, and succeeded in finding time to keep up with the advance in medical literature.

It is to be regretted that he did not write more. His paper on "Dengue," in the sixth volume of the Transactions of the American Public Health Association, is an admirable contribution to the discussion of that obscure and most distressing malady.

His opinions, oral or written, on the medical questions of the day, were always marked by freedom from passion, and by a plain intention to avoid, on the one hand, the bondage of prejudice, and on the other hasty deduction and restless change. While he was alive to every good impression and suggestion of progress, he was deliberate and judicial in committing himself to that which was new. His honesty and prudence were manifested in these and many other ways, and his patients and professional brethren trusted him implicitly, and were not disappointed.

His personal appearance was most attractive and commanding. Tall in stature, he was erect and vigorous in his carriage, impressing even casual observers with the fact that he was a man of more than ordinary force. He carried a good head above broad shoulders; his face was "benignant and serious," and on his manly features a light was radiant which came from a good heart. There was an indescribable quality in his presence and manners which won the confidence of all, but especially impressed and charmed his friends and companions.

It is a source of joy and inexpressible satisfaction that there are so many good and true men in the medical profession of the United States. The whole fraternity may well join in thankfulness that the career of Dr. Thomas among his colleagues, neighbors, and friends was blessed as it was to his family, his patients, and the State; that he attempted with so much modesty and unflinching purpose to realize in his daily work and in his public services so high an ideal, and that his last professional act, in the performance of which he gave his life, included the grand idea of the brotherhood of nations and the community of science and benevolence.

From those who knew him well, the source of the power in his life was not hidden; it sprung perpetually from an humble belief, not only in the supernatural, but in a personal, triune God, upon whose mercy he had cast himself and whose law he strove to know, to love, and to obey. C. R. AGNEW.

MISCELLANEOUS

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY, FROM FEBRUARY 7, 1885, TO FEBRUARY 13, 1885.

Town, T. L., Major and Surgeon, granted leave of absence for twenty days. (S. O. 14, Dept. of Texas, Feb. 4, 1885.)

Wilson, Wm. J., Captain and Assistant Surgeon, ordered for duty as Post Surgeon, Fort Preble, Me. (S. O. 27, Dept. East, Feb. 5, 1885.)

Woodruff, Ezra, Captain and Assistant Surgeon, ordered from Willet's Point, N. Y. Harbor, to Dept. of Dak.

Taylor, Marcus E., Captain and Assistant Surgeon, ordered to Dept. of the Mo. (S. O. 30, A. G. O., Feb. 5, 1885.)

Robinson, S. Q., Captain and Assistant Surgeon, from Portland, Oregon, to his proper station, Fort Spokane, W. T. (S. O. 20, Dept. of Col., Feb. 2, 1885.)

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDING FEBRUARY 7, 1885.

Long, W. H., Surgeon, relieved at Detroit, Mich., to proceed to Chicago, Ill., and assume charge, Feb. 4, 1885.

Godfrey, John, Passed Assistant Surgeon, to proceed to Vicksburg, Miss., and Memphis, Tenn., as inspector, Feb. 6, 1885.

Bennett, P. H., Assistant Surgeon, to assume temporary charge of the service at Detroit, Mich., Feb. 4, 1885.

Williams, L. L., Assistant Surgeon, to report to the Officer in charge at Detroit, Mich., for temporary duty, Feb. 7, 1885.

RESIGNATION.

Miller, T. W., Surgeon, resignation accepted by the Secretary of the Treasury, to take effect March 1, 1885, Feb. 4, 1885.

PROMOTION.

Godfrey, John, Passed Assistant Surgeon, promoted and appointed Surgeon by the Secretary of the Treasury, from March 1, 1885, Feb. 6, 1885.

APPOINTMENT.

Williams, L. I., M. D., of South Carolina, having passed the examination required by the regulations, was appointed an Assistant Surgeon by the Secretary of the Treasury, Feb. 6, 1885.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED FEBRUARY 14, 1885.

Guiteras, John, Passed Assistant Surgeon. When relieved at Key West, Fla., to proceed to Charleston, S. C., and assume charge Feb. 11, 1885.

Kalloch, P. C., Assistant Surgeon. To report to Passed Assistant Surgeon Peckham at Wilmington, N. C., for examination for promotion Feb. 10, 1885.

Glennan, A. H., Assistant Surgeon. Relieved from duty at New Orleans, La., to proceed to Key West, Fla., and assume charge Feb. 11, 1885.

ASIATIC CHOLERA---SOME ACCOUNT OF ITS HISTORY, NATURE AND TREATMENT

BY FRED HUMBERT, M D, F C S, ALTON, ILL

It is the duty of a physician who has lived and practiced in several epidemics of Asiatic cholera to give his impressions and experience So long are the intervals between the visits of this disease, that it cannot be studied clinically, and so a majority of present practitioners have never seen it But they must prepare to meet it, and very probably the coming year I have, as clearly as possible, given a pen-picture of it as it passed before me on several occasions, hoping it may be to young physicians, for whom it is written, of some value in time of need

When the cholera first appeared in Europe, in 1830, the physicians were at a loss how to treat it

They searched the reports of the English physicians in the East Indies, where the cholera had been since 1817 under observation, but found little information Having no better resources, they adopted their crude, heroic treatment But soon experience of their own, of a very painful nature, drove them from this The alarming mortality of the cholera in that year, as it traveled from Asia through European Russia and Poland toward the center of the continent, is not to be wondered at when we recall the remedies applied Venesections of a pound and a half at first, and later in smaller quantities, till blood refused to flow, mustard poultices over the bowels and legs, leeches to the abdomen, and behind the ears, burning on the bowels paper saturated with alcohol, or dropping on them melted sealing-wax, besides bathing patients in a warm solution of liquor caustic

Internally, twenty or thirty grains of calomel, in repeated doses, was administered until at times, in the then seldom made post-mortem examination, ounces were found in the intestines Opium (generally in the tincture) was so freely administered that the patient never rallied from the narcotism Mucilaginous drinks were freely given

After trying these remedies in vain, the European physicians resorted to astringents, stimulants and opium in small doses (2 to 5 drops of tincture) Sulphuric acid, a remedy long before freely used in diarrhœa, typhus and scarlatina to restore the chemically changed blood to its normal state, was resorted to here also Tinctures of cardamon, catechu, capsicum, cantharides and camphor, chloroform, emetics and escharotics, calomel and castor oil In collapse, hydrocyanic acid, brandy and-chalk mixture and turpentine were used Of all these remedies, the stimulant tinctures of camphor and cantharides are most valuable The patient was wrapped in blankets wrung out of warm or cold water

Hypodermic injections of opium have been resorted to for a long time

Lately, hypodermic injections of large quantities of water, from two to four ounces, have been experimented with

But before being justified in the use of such heroic treatment, we must ask, Where does the chemical separation of the blood take place?

Is it in the lungs or in the arteries, after the venous blood has passed, aerated or not aerated, through the lungs, having left more and more the solid parts in the arteries?

Or does this separation begin contemporaneously in the whole circulation? It is found in post-mortem section of cholera bodies as a dark, syrup-like fluid without fibrin, having in the veins and arteries dark-brown lumps Gradually, as the separation increases, the fluid necessary to life is destroyed

Can hypodermic injections into the areolar tissue, or infusion with a tap into the peritoneum of water or medicated water, be used in sufficient quantities to replace and correct the first or greater discharges of rice water by the bowels, not to speak of that which is vomited? Can it restore the already separated fluid? The course of the cholera is rapid There is no time for these injected remedies to be absorbed, even if, as has been well said, it were possible to keep the cramping, restless patient quiet long enough to administer them Will it not follow in the same rapid course towards the intestines? But can it be prosecuted in an epidemic in which the practitioner is called every half-hour by day, and oftener at night, to other patients? Can such operations be left to the nurse or family in a time when the morale of the community is out of joint, help rare, friend forsaking friend, husband wife, and parents their children? Often the nurse has yielded to the temptation of the plentiful stimulants

The majority of cholera patients are not found in well regulated hospitals or in palatial residences

There are floating in the present medical literature, since the cholera is reasonably expected to visit our continent from Europe next year, many theories etiowell, to attend a meeting in the city of Washington to complete the arrangements for the International Medical Congress to be held in that city in the year 1887

He was taken ill on the railway train near Richmond, but continued on to his destination After reaching Washington his malady took the form of pneumonia His good wife was sent for, his sympathetic medical brethren aided her in her affectionate and devoted ministrations At one time the disease seemed to be checked, but the arrest was only simulated, he grew weaker, and on the morning of Saturday, December 6, 1884, he departed this life, following, as we have credible evidence, those who have endeavored to imitate the Good Physician

ASIATIC CHOLERA---SOME ACCOUNT OF ITS HISTORY, NATURE AND TREATMENT

BY FRED HUMBERT, M.D., F.C.S., ALTON, ILL.

It is the duty of a physician who has lived and practiced in several epidemics of Asiatic cholera to give his impressions and experience. So long are the intervals between the visits of this disease, that it cannot be studied clinically, and so a majority of present practitioners have never seen it. But they must prepare to meet it, and very probably the coming year. I have, as clearly as possible, given a pen-picture of it as it passed before me on several occasions, hoping it may be to young physicians, for whom it is written, of some value in time of need.

When the cholera first appeared in Europe, in 1830, the physicians were at a loss how to treat it.

They searched the reports of the English physicians in the East Indies, where the cholera had been since 1817 under observation, but found little information. Having no better resources, they adopted their crude, heroic treatment. But soon experience of their own, of a very painful nature, drove them from this. The alarming mortality of the cholera in that year, as it traveled from Asia through European Russia and Poland toward the center of the continent, is not to be wondered at when we recall the remedies applied. Venesections of a pound and a half at first, and later in smaller quantities, till blood refused to flow; mustard poultices over the bowels and legs; leeches to the abdomen, and behind the ears, burning on the bowels paper saturated with alcohol, or dropping on them melted sealing-wax, besides bathing patients in a warm solution of liquor caustic.

Internally, twenty or thirty grains of calomel, in repeated doses, was administered until at times, in the then seldom made post-mortem examination, ounces were found in the intestines. Opium (generally in the tincture) was so freely administered that the patient never rallied from the narcotism. Mucilaginous drinks were freely given.

After trying these remedies in vain, the European physicians resorted to astringents, stimulants and opium in small doses (2 to 5 drops of tincture). Sulphuric acid, a remedy long before freely used in diarrhœa, typhus and scarlatina to restore the chemically changed blood to its normal state, was resorted to here also. Tinctures of cardamon, catechu, capsicum, cantharides and camphor, chloroform, emetics and escharotics, calomel and castor oil. In collapse, hydrocyanic acid, brandy and-chalk mixture and turpentine were used. Of all these remedies, the stimulant tinctures of camphor and cantharides are most valuable. The patient was wrapped in blankets wrung out of warm or cold water.

Hypodermic injections of opium have been resorted to for a long time.

Lately, hypodermic injections of large quantities of water, from two to four ounces, have been experimented with.

But before being justified in the use of such heroic treatment, we must ask, Where does the chemical separation of the blood take place?

Is it in the lungs or in the arteries, after the venous blood has passed, aerated or not aerated, through the lungs, having left more and more the solid parts in the arteries?

Or does this separation begin contemporaneously in the whole circulation? It is found in post-mortem section of cholera bodies as a dark, syrup like fluid without fibrin, having in the veins and arteries dark-brown lumps. Gradually, as the separation increases, the fluid necessary to life is destroyed.

Can hypodermic injections into the areolar tissue, or infusion with a tap into the peritoneum of water or medicated water, be used in sufficient quantities to replace and correct the first or greater discharges of rice water by the bowels, not to speak of that which is vomited? Can it restore the already separated fluid? The course of the cholera is rapid. There is no time for these injected remedies to be absorbed, even if, as has been well said, it were possible to keep the cramping, restless patient quiet long enough to administer them. Will it not follow in the same rapid course towards the intestines? But can it be prosecuted in an epidemic in which the practitioner is called every half-hour by day, and ofterer at night, to other patients? Can such operations be left to the nurse or family in a time when the morale of the community is out of joint, help rare, friend forsaking friend, husband wife, and parents their children? Often the nurse has yielded to the temptation of the plentiful stimulants.

The majority of cholera patients are not found in well regulated hospitals or in palatial residences.

There are floating in the present medical literature, since the cholera is reasonably expected to visit our continent from Europe next year, many theories etiological and some therapeutical which may be read and studied in the room of the student, but are of no practical value to the young practitioner He has to face this curse of the human family, and needs weapons

It may not be out of place for the writer to give the practical results of his observation and experience during four epidemics of cholera, in two of which he spent nearly all his bodily strength in attendance on patients day and night

From the researches of Hayem, of Paris, in microscopical examinations of the blood of cholera patients to Koch's last results in which he found that the specific poison is a kind of spirillium rather than a bacillus, limited to the mucous skin of the intestines and is not found in the mesenteric glands nor in the blood It is only the result not the cause of the disease Where, then, is the separation or chemical separation of the serum from the solids of the blood? Is it in the mucous membrane of the intestines or in all the capillary vessels of the system? Does this separation begin gradually in the minute vessels and more and more as it reaches the larger vessels leave the solids of the blood and permit only the serum to pass on to the intestinal canal to be accumulated until expelled? It is thus the channel of drainage for the system in normal life when the fountain of the kidneys is stopped How, then, can this spirillium, found only in the mucous skin of the intestine, destroy life? We have not gained any facts from these chemical and microscopical researches to aid us toward a rational treatment of Asiatic cholera We have learned practically to prevent and lessen its malignity by the researches of the sanitary branch of the political economists, as seen in the epidemic of 1874 in Europe

We know now that by the decomposition of animal and vegetable matter in the soil around houses, cesspools, manure heaps, stagnant ditches and sewer-openings, under proper atmospheric and telluric conditions, the fermentation of the fungus of cholera-poison is bred and transported In localities where proper sanitary improvements are instituted, this disease has lost its malignity, and by further general and systematic sanitary provision, the sting of this scourge may be removed [1]

An epidemic of cholera is fearful in its mortality from its commencement to its acme, and its departure, as statistics prove, is almost always gradual The laity, and even some physicians, concluded from this that the profession, if not responsible, are incompetent or helpless in this disease This is a most unjust charge against a profession which, regardless of self-preservation, is devoted entirely to assisting the helpless victims of this malady, without regard to social distinction We readily see the injustice of this accusation, when we remember that not every cholera case comes under the care of the physician, and many who do come only in a collapsed or moribund state

Often they have been supplied from the drug-store, which early, before a cholera case occurred, in anticipation of a money harvest, advertised by the press and over the counter their nostrums as unfailing remedies These are not held responsible for the dead, due directly or indirectly to their prevention of the attendance of a qualified physician

Our profession should be careful in publishing a treatment as successful, before being proved so by the recovery of a majority of the cases under its influence in the epidemic then raging How unwise to rush into print and claim a specific after the treatment of two or three cases It is only after a fair trial that a remedy can be entitled to the confidence of the profession We should not forget the truism—"different people have different resistance"

The vital force in our organizations is more or less developed, and, as every physician knows, plays an important part in the good result of remedies Frequently a physically frail-built patient, struggling under a dangerous malady, comes up from the brink of the grave, while another, well developed and robust, with the same malady and under similar treatment and surroundings, succumbs The latter had not the tenacious hold on vitality of the former

I have seen in cholera epidemics and at other times many unexpected recoveries After setting aside my remedies, continuing only the careful feeding to sustain life, and with little hope, I have seen the vacillating, flickering flame rally Success in these cases may add nothing to the physician's prestige, but they establish the fact that some patients *will not die*

In the fifty years just past, when Europe has been threatened by a visitation of Asiatic cholera, the question of its contagiousness has repeated itself This prevents the early and proper regulations by sanitary efforts for its prevention and control State authorities lean toward the non-contagious theory, for quarantine paralyzes commercial traffic and money is lost Now, setting aside hairsplitting theories, we dare not dispute that the disease is transportable Another fact which prevents timely prevention, is that the first case is almost always declared by the attending physician and local authorities to be cholera-morbus, or at least it is denied to be Asiatic cholera It is known that epidemics of all kinds vary their symptoms more or less from time to time The main symptoms always remain, as red is always red, whether the color be a shade lighter or darker

Symptoms —The premonitory symptoms of Asiatic cholera are few, well marked, and more easily detected than those of measles, scarlatina, varioloid, variola, typhoid or typhus fever They exist but a short time till the disease is perfectly developed They begin with oppression in the temporal region, ringing in the ears with difficulty of hearing, a dull expression of the eyes, shivering sensations, oppression in the region of the heart and stomach and nausea After these symptoms have lasted an indefinite time, more or less marked according to temperament and intensity of the poison, a rumbling, like

---

[1] 'Mr David Richard in his late experiments on pigs comes to the conclusion that the alvine discharges at certain stages of cholera contain a powerful poison whose chief function is to enfeeble and destroy the function of respiration—that the rapidity of its action excludes it from being an organism He thinks it a chemical compound probably an albuminoid He thinks the evacuations easily disinfected, probably by permanganate of potash

'Although the poison decomposes, it might by desiccation retain its power for some considerable time in clothes etc stained with choleraic discharges —*Indian Medical Gazette*, April 1884

in

water rolling along the transverse colon, with or without pain in the gastric region, with oppression in the chest and a slight dyspnœa, sets in These symptoms are greatly relieved by the first large watery motion mixed with the contents of the bowels This relief is so great for a time, many are deceived, and defer calling medical aid till too late From this time or earlier there is suppression of the secretion of the kidneys, and no urine will be discharged till recovery begins The next symptom is a large, turbid, thin evacuation, called the rice-water discharge In the height of the disease the discharges are as clear as well-water There is no sign of bile in any of the evacuations after the first It is retained in the gall-bladder and the ductus hepaticus No absorption of it seems to have taken place Nearly all absorption has apparently ceased I was called to see a farmer a mile and a half from town The hired man was lying dead on the porch, while the farmer and his wife were in bed, in agony with cholera Only one neighbor was present to assist The wife was 28 and the husband 40 years of age The disease had not so far advanced with the wife as the husband While I administered medicine to the husband, I observed the wife go to the night vessel, by the help of the neighbor This she did twice Shortly after, as I sat by the bed attending to her, I looked into that porcelain vessel nearly full which she had just evacuated, and dropping a pin into it, could see it distinctly at the bottom The primary symptoms before the rice water discharges set in, last from one to twenty-four hours During this time medical aid is most successful Under the present stimulant-narcotic treatment, this is the only time when a cure can be reasonably expected

Vomiting begins either with or before the first rice-water discharge The first vomit consists of the mixed contents of the stomach, the next has in it some mucus, but both are free from bile These are followed by clear fluid with the drinks swallowed The oppression in the stomach and dyspnœa increase Pain in the bowels, cramps in the arms and legs, restlessness, shrieks from the patient now begin or increase with copious vomiting and purging The skin becomes dry and cold, the eyes red with a blue ring around them, and the pulse diminishes After this has continued from one to six hours, sometimes longer, the vomiting and purging decrease in quantity and frequency This is most distressing to witness The patient is in painful agony and oppression He springs up in bed only to fall back exhausted, repeating it again and again while the watery stools pass under him He is tormented with thirst while he continues to call in a hoarse whisper for water Such torment and suffering are seen in really no other disease

Now the face takes on a blue leaden hue The cramps of the extremities are not so severe The skin becomes ice cold and covered with clammy sweat The skin of the hands, forearms, feet, and legs is cold and of a dark blue color and wrinkled by shrinking, looking like hands after a whole day's washing This is the height of the stage of true collapse

He is indifferent to all his surroundings, even to his own family I have never seen a patient after the rice-water discharges appear make his will He dies in this condition perfectly conscious, but sometimes falls into coma and passes away Sometimes after remaining twenty or twenty-four hours in this state the pulse fills again, the breathing becomes normal but feeble, the hands fill up, the temperature increases, the circulation returns, the whole body gets warm, the red hue of the skin appears, and in two or three days you see the patient out of bed without any lesion to trouble afterwards In this state of coma many are buried by the panic stricken people who are not dead Let me give a case in proof A patient in the beginning of collapse was buried against my urgent advice I was called at 8 oclock A M, to a young mulatto, 17 years of age, who, with her husband, were servants in a merchant's family Both had cholera and died I found her in the beginning of collapse, having had the second evacuation At noon I passed a coffin one fourth of a mile from the house and was told the negro woman was dead I drove directly to the house and entered the room where the woman lay The entirely nude body was covered with a sheet It lay like a marble statue, face chest, bowels, arms, and legs full, without any shrinking, the skin having the mellow yellow color so characteristic of a young mulatto It was of no avail that I urged delay in her burial, before 2 o'clock she was under the ground How many such burials take place among a panic stricken people[1] They are hard to prevent in this country where permits are only needed in the larger cities Do many physicians in the cities who grant certificates see the subject?

And now when we collect all the symptoms into one picture and add our own experience to form a diagnosis we come to the conclusion that we have here a shock of the nervous system—prominently the sympathetic But when we try to explain how this chemical separation and discharge of fluid takes place only by the mucous membrane of the intestines we work in the metaphysician's region of the immaterial and unfathomable law of nature

Before we speak of treatment, a few words on prevention

Complete and daily disinfection of all water-closets, refuse barrels and sewers Immediate removal of all excremental matter after being disinfected with sulphate of iron or carbolic acid, and covered with pulverized animal charcoal or dry earth The rooms should be purified by the burning of crude sulphur, but in such small quantities that the diluted sulphuric acid will not excite coughing Exert a moral influence Abstain from beer, from large draughts of water, ice water, lemonade and ice cream In cholera epidemics the greatest mortality is on Mondays, from the free use of these things on the day preceding I have seen many young girls and others' in full health on Sunday morning, after spending the day in the use of these luxuries and dissipation, die with the cholera on Monday The diet should not be changed, unless it be to use fruit moderately Cabbage and green vegetables should be avoided Those used to liquor should use it moderately, and those who are abstainers abstain Brandy is only to be used as a medicine I have seen clergymen, during these epidemics, under the influence of liquor on the streets Keep from exposure to cold, wearing woolen next the feet and body Watch yourself and household for the first appearance of illness As a prophylactic and pleasant drink, use largely diluted sulphuric acid, sweetened if desired, and flavored with orange Let this be kept in public places and at home as a summer drink If attacked by cholera when from home, take an aromatic astringent drink, and call your physician

---

[1] Previous to the year 1870 in the immediate vicinity of Bordeaux, France, several workmen in excavating in a churchyard, came upon a belt of ground apparently impregnated with some antiseptic material All the bodies in the belt to the number of about 200 were found to be almost as perfect as when buried, I found when visiting the crypt of the cathedral where shown One was found lying on its side, the legs drawn up nearly to a level with the abdomen while the arms were in such a position as to indicate that both these and the legs had been used in a desperate but futile effort to push out the side of the coffin, whilst the look of horror remaining on the face was simply indescribable In the other case the body was found lying on its face the arms extended above the head, as if attempting to push out the top of the coffin —*Lancet*, June 10, 1884

But one of the most important prophylactic measures, in town or city, would be for the board of health to appoint a committee of sanitary composed of philanthropic citizens Let them have authority to examine every house and report to the board every foul place This committee should also freely distribute printed instructions among the people

Treatment—The most important thing for the physician to consider when called to the bedside of of a patient with this short-lasting disease, is, How can I change the abnormal and rapid secretion of the mucous membrane of the intestines and rally the sinking patient? Such remedies as will in the commencement of the characteristic rice-water evacuations fulfill the indications and promise to reduce the mortality But a drug which, in this disease as in all others, will cure every case will never be found Drugs are used for two purposes in the treatment of cholera—to disinfect and for administration For the latter purpose the majority of physicians use the stimulant, narcotic and astringent remedies Only a small number *experiment* with other drugs Still, there are some who obstinately hold on to the old idea that calomel is a universal remedy for all ills They ignore the teaching of all post-mortem reports since 1817 as to its failure and positive harm

It is not true that if it does no good it will do no harm When introduced into a living organism, if dissolved, it must impoverish the little remaining blood, and if not dissolved, it accumulates in the stomach and intestines and acts as a foreign body[1] In this rapid disease, with its low vitality, such a condition hinders the feeble reaction and prevents the use of other remedies It requires a stretch of imagination to believe, as Dr Ayre says, that two grains of calomel placed on the tongue every five or ten minutes, and washed down with an effervescing draught, will do any good But calomel can be of service and do good when other drugs may do harm, when reaction from collapse appears Then, given in small doses every hour or two for a few times, it will help to restore the suspended mucous secretion

Opium, when given to control diarrhœa or nausea and vomiting, in large repeated doses, has proved injurious It paralyzes the vital force and increases mortality Laudanum in 5 to 10 drop doses hourly, is 60 to 120 drops in twelve hours After the first dose copious vomiting sets in, soon becoming less, while the pulse gets fuller, but remains small and weak The head is hot, the eye glassy, the coating on the tongue thicker, the sensorium dull, while the extremities remain ice cold Stupor and diarrhœa increase, and life ends in coma But coma should not be the finale of cholera The mind remains nearly always unimpaired where no narcotic is given But in the premonitory symptoms opium can be judiciously used, and also as a narcotic and stimulant on the first indication of collapse Still, opium should not be long continued, for its cumulative effect is to produce stupor, ending in torpor and death Hypodermic injection of morphine is the same in its effect as opium, only more rapid and uncontrollable It lulls the pain, but the disease in the majority of cases in which it is given runs its course, like a smothered fire A correspondent in your journal says "morphia is the king of nervous remedies," and recommends it in cholera To this I strongly object For the last ten years I have seen it freely and often injudiciously used by our young practitioners Placing morphine on the bottom of the cork of a drachm vial of morphine and calling it a sixth of a grain, and in other careless measurements, then injecting, often brings the patient to the danger line, and in two cases under my observation beyond it No 1, a young woman 22 years of age, in which the morphine injection was given in the evening to relieve a headache, which of course it did The next morning her husband found her dead by his side No 2, a lady in the prime of life and perfect health, surrounded with comfort After a hearty breakfast she suffered from a slight pain in the stomach—indigestion I called, and gave ipecacuanha and two $^1/_6$-grain morphine powders, one of these to be given at 2 o'clock, and the other five hours after, if not relieved In the evening about 10 o'clock a fashionable doctor was called to a patient in the same house He offered to relieve her pain immediately, and administered a morphine injection The next morning I was called at 7, and found her dying Therefore I cannot indorse that morphine is king It is only uttering again the errors of the fathers of our art of fifty years ago They believed that calomel in fever and venisection in inflammatory diseases were king and queen of all ills And what misery I have seen follow these!

Dr F P McFarland gives the result of thirteen years' experience in India (Dublin *Jour of M S*), in which he says more cases have recovered under the salt treatment than under any other

There are two ways of using the salt The first mixture, which he considers the best, is Common salt, dr 2, bicarbonate soda, gr 36, chlorate potassi gr 10, and water, 8 ounces, to be taken every half hour or hour The second is half an ounce of common salt in a pint of water, every half hour or hour (*Jour A M A*, Vol 2, page 295, 1884)

---

[1] Dr Joseph Heine military surgeon in the temporary hospitals of Papanz, Poland in 1831, made a section of the body of a soldier who had died of cholera after two days treatment with sulphate of zinc In the stomach he found several tablespoonfuls of a whitish grey fluid At the bottom of the stomach he was able to detach without tearing half of a white membrane the width of a hand It was a croupous membrane of from 1 to 1½ lines in thickness, and on it there were not missing the blood dots or islets

The permanganate is a poisonous disinfectant, claimed to destroy poisonous emanations It is recommended in diarrhœa, scarlatina, diphtheria etc, and lately in East India, in ¼ to ½-grain doses, in water, several times a day As before stated, this has been experimented with in a few cases, and I do not recommend it

Sulphuric acid is used only as a drink in the manner already described

Boracic acid is highly commended by W I Butler, of the Indian service, Madras He said, as the pure acid was not procurable, the biborate of soda was at first used, and 70 to 75 per cent recovered Afterward, when the pure acid was used, all recovered It was used in ten-grain doses, combined with biborate or bicarbonate of soda Salicylic acid in 10 grain doses, combined with 5 grains of bicarbonate of soda, and 5 grains of carbonate of ammonia, in an ounce of water, is recommended

Capsicum was early, and is still, used I have given it—capsicum, grains 3, bicarbonate soda, 20 grains, water, 4 ounces, give a tablespoon every half hour, or hour, as an auxiliary to other medicines, to allay vomiting

In the epidemic of 1866, Dr Spinzig, St Louis City Hospital physician, says, in report of treatment, August 27, when the disease was at its height, nine were given tincture cantharides, 5 to 20 drops every hour or two, none died September 12—Sixteen were so treated, twelve recovered and four died October 10, when the disease was on the decline, twenty two were treated and nineteen recovered This tincture was used in Europe in 1831, in very small doses, without any good result

Liebig soup was extolled by some physicians as a cure Collodion treatment An external application of collodion, 6 drachms, castor oil, 1 drachm, M, and smear the abdomen, covering with cotton-wool A French physician used and recommended this as a cure for diarrhœa and light cholera I mention it as a curiosity (*L'Union Medicale*)

Castor oil is very warmly commended by some English physicians It is used in moderate doses when the power of elimination is active Seldom more than two or three doses are said to be necessary It is said to be very efficacious in diarrhœa, before the cholera symptoms appear

Tartar emetic and ipecacuanha are reported as successful in many cases But how many of the recoveries, after using these last named remedies, are the result of, and due to, the *vis medicatrix naturæ?* Drenching the bowels with water by the mouth is reported as successful, and as an improvement, using the hypodermic syringe to inject medicated water into the subcutaneous areolar tissue But to more quickly reach the center of the supposed cause of cholera, infiltration, by means of an aspirator, of the peritoneal cavity with artificial serum has not been tried An effort is made to replace the rapidly wasted fluids This I only allude to here as a novel therapeutic addition to the literature or the art and science of medicine

Camphor and chloroform, which are used separately by many physicians as favorite remedies, I have referred to last, because *combined* they have proved valuable remedies to me, not only in Asiatic cholera, but also in many other diseases where a sedative stimulant, and may I say also astringent remedy, were indicated I have received more satisfaction in a long practice from its use than any medicine of its class I present it with much confidence, not claiming it as an arcanum

Knowing how unsatisfactory was the treatment in Europe during the epidemic of 1831, I tried in 1848 to procure the best information possible in this Mississippi valley In the course of my research I found in the January number of 1848 (when the Asiatic cholera appeared to an alarming extent and of a malignant type in Europe) of the *American Journal of Medical Science*, vol 1, page 170, the following article "Champhor and chloroform mixture by F and H Smith, M J, and Retrospect of M S, Nov, 1848 There is great difficulty or rather an utter impossibility of administering camphor in a state of solution in doses of sufficient potency in some cases The form of pills, the only mode of giving large doses of the medicine is objectionable in many cases and in others altogether inadmissible The camphor, being merely in a state of mechanical division, on being set free in the stomach, from its extreme lightness quietly separates and floats about, thus producing in many cases *much local irritation* in that organ, instead of soothing or arousing the general system

"Messrs F & H Smith, chemists of Edinburgh, give a formula for exhibiting camphor in doses of almost any amount of strength—certainly as large as any case can require—and that in perfect solution, thereby allowing of a nice adaptation of the dose to the circumstances of each case The formula is as follows Three drachms of solid camphor are dissolved in a fluid drachm of chloroform This is, perhaps, one of the most remarkable cases of solution the whole range of chemistry presents to us The solution is most rapid and complete and the bulk of the liquid is now increased from one to fully four liquid drachms This solution rubbed up with the yelk of one fresh egg may be formed into an extremely elegant emulsion by the addition of water without the slightest separation of camphor or chloroform, in fact no separation of any kind takes place If to the proportions given above as much water be added as to make a four-ounce mixture, each teaspoonful of the mixture when formed will contain about five and a half grains of camphor and about two minims of chloroform This mixture can be administered in any ordinary vehicle, such as water, without any separation, indeed the mixture is readily and completely effected, as cream with tea or coffee"

This struck me favorably on account of the perfect chemical solution of the camphor in chloroform, a pleasant stimulant and a gentle astringent of two sedatives of great volatilization I had found that for which I searched to replace the strong astringents, tannin, gallic-acid, ammonium, pepper, brandy, alcohol, and that powerful one, lead

When cholera reached us in 1849, I administered this camphor mixture in the premonitory stage in all cases and in the beginning of collapse It relieved the oppression in the gastric region, the flatulence, nausea, vomiting and diarrhœa I prescribed every hour a teaspoonful with two drops of laudanum so long as the premonitory symptoms lasted, and afterward, if no collapse, I gave it every two hours with one drop of laudanum, for a short time If collapse set in I gave the mixture every hour without the laudanum, but added instead every half hour or hour a teaspoonful of the following

℞	Capsicum powder	gr iii
	Bicarbonate of soda	ʒii
	Water ,	℥iv

But if this failed I used instead of it, tinc cantharides, 10 drops every half hour In making the mixture of camphor I used 2 drachms of chloroform instead of 1, I never united the laudanum with the mixture, but dropped it into the teaspoonful of the mixture, so that it could be used without the laudanum when needed

During the past thirty-five years I have used this mixture without laudanum in almost all cases of diarrhœa—except feculent—in which I give it after the action of an aperient I use it in small doses with other medicines in diarrhœa of children, and use it in all diseases where camphor is indicated Of all the mixtures in which no alcohol is used it remains most free from ferment, does not separate and lasts for years if kept from frost

But we cannot depend upon drugs alone for success Drink, food and external appliations play a very important part in the treatment if judiciously used Especially is this true regarding the temperature and quality of the water used as drink

It always seemed strange to me that ice should be recommended—pieces in the mouth and ice water to drink and alternating hot medicines with pieces of ice in Asiatic cholera

Cold water cannot produce reaction, invigoration or warmth to the parts to which it is applied, when the heat is under the normal and the vitality at the lowest ebb, as in cholera Ice satisfies thirst only for a very short time At first it creates a burning sensation, pleasant to the drinker, but when it is melted the burning sensation is gone and the desire for more is craving Cold or ice water can only be used when the temperature of the body is above the normal and the vitality must not be below its normal stage It is contra-indicated when chilliness prevails When ice water is introduced into the torpid stomach, it must destroy that small spark of vitality left About the same is true of warm water It never produces a sensation of warmth, but diminishes it and relaxes where the heat is under the natural standard Instead of being a stimulant it is a nauseant I have long held that warm water encourages vomiting, while hot water allays and stops it Hot water is a decided stimulant, increasing the circulation, as seen in gynæcology a remarkable astringent I use it and recommend its use in Asiatic cholera At first I give it freely between the medicines, in doses of a teaspoonful or dessert spoonful of clear hot water, free from any smell, so as *not to be offensive* As the sickness advances I give it in tablespoonful doses It is a decided sedative to the stomach, acting far more rapidly than narcotics At first the patient may refuse it and desire cold or ice water, but soon he realizes the good effect of the hot water and asks for it In the collapse I give between the medicines, every half hour, a teaspoonful of the yelk of a fresh egg with milk Leibig or beef soup in four ounces, of which I mix the yolk of a fresh egg and some brandy and hot water, and egg-nog I also use When reaction sets in I increase the quantity Now I also administer, every two hours, two grains of calomel combined with bicarbonate of soda Warm baths can hardly be used in private practice The undressing and dressing of the patient, heating the water in such quantities, procuring a bath-tub, and lifting the patient in and out with so little help make this a very difficult proceedure

I always order calico wrung out of hot water to be wrapped around the extremities and covered over the bowels, and this repeated often, that they keep hot Bottles filled with hot water placed around the body and between the limbs are a good appliance When none of these can be had, I have learned from the old ladies that boiled ears of corn wrapped in domestic are as good and retain heat longer than the bottles In all this treatment the patient must lie in a horizontal position and keep as quiet as possible, speaking only encouraging words Cholera seldom leaves any lesion, but sometimes the patient goes into a secondary fever Still, this is so rare that the treatment is best left to the judgment of the attending physician As the judge said in his final charge to the jury "If you think this, you must do that, but if you think that, you must do this" There is one fact to be mentioned of some importance A month or six weeks after the cholera disappeared, our section of the country was nearly free from febrile diseases After that, bilious intermittents appeared, when, if as usual a cathartic was given, it would produce a copious watery evacuation with bile This prostrated the patient In about twelve to twenty hours another of the same character would be dejected, typhoid symptoms would set in, ending in coma and death, generally in four days I have seen in the same season several puerperal fever cases, which ran a similar course It seemed as though a type of cholera still remained

November 4th, 1884

METHODS OF TREATMENT OF RESISTANT CLUB FOOT

BY E H BRADFORD, M D, BOSTON, MASS

Read in the Section of Surgery and Anatomy of American Medical Association May, 1884

Certain cases of neglected club foot are occasionally met of such an obstinate character as to resist ordinary treatment by tenotomy and mechanical appliances or to demand constant attention for a long time before a satisfactory result is gained This has given rise to bolder operative interference than has before been thought justifiable The following tables contain all the cases of tarsotomy which the writer has been able to collect

TABLE OF OPERATIONS ON THE TARSUS FOR THE RELIEF OF RESISTANT CLUB FOOT —REMOVAL OF THE CUBOID BONE

The above table, compiled with additions from Chauvel's excellent article on the subject (*Archives Generales de Medecine*, 1882, p 456), shows that the danger as to life from these operative procedures is not great In 110 operations on 88 patients, 3 deaths are recorded One of these is not fairly attributable to the operation (case 23), as at the autopsy evidence of ulcerative endocarditis existing before the operation, was found The other deaths, from septicæmia and hospital gangrene, might possibly have been prevented if antiseptic precautions had been used (cases 8 and 1) It is, however, difficult to determine, accurately, as to the exact amount of correction of the deformity and ultimate benefit afforded by the operation, from the comparatively meager reports given in many cases Two of the patients subsequently underwent amputation, showing that the result was not satisfactory, but a large majority of the cases were permanently benefited In the writer's two cases (three operations) this was certainly the case, the patient having been heard from three years after operation The improvement in the position of the foot in the first case was not as great as in the second, owing to improvement in the technique In both, however, an ugly deformity was converted into one hardly noticeable, with perfectly useful feet, the patients, from walking on the dorsum of their feet, being made plantigrades

The methods introduced may be grouped as follows

1 Removal of the cuboid alone
2 Removal of the astragalus alone
3 Removal of the astragalus and cuboid and scaphoid
4 Section of the neck of the astragalus
5 Removal of the astragalus and the external malleolus
6 Osteotomy of the lower end of the tibia and fibula
7 Wedge shape resection of the tarsus

The results from the first method have not been altogether satisfactory, and the fourth may be said to be insufficient, and against the third and sixth it may be urged that too much mutilation of the foot is required

Authorities differ in advocacy of the second and seventh methods

Ried (*Deutsche Zeitsche f Chir*, 1880, v iii, 114) states his preference for the removal of the astragalus over a wedge shaped section of the tarsus, but admits that the matter is yet *sub judice*

Rupprecht (*Centralblatt f Chirurgie*, 31, 1882), speaking from experience in twenty-seven operations, is decidedly in favor of the former of these methods on clinical grounds, that in five of the nine cases of resection of the tarsus a tendency to inversion of the front of the foot remained, while after the eighteen excisions of the tarsus he performed this was not the case, and also because the astragalus, the bone whose distortion is chiefly instrumental in causing the deformity, is not thoroughly rectified by wedge-shaped section of the tarsus He admits, however, that in certain cases, especially in those above 13 years of age, extirpation of the astragalus alone is not sufficient, but that the scaphoid and several of the cuneiform bones must also be removed Sometimes a portion of the external condyle should also be removed In severe cases in the ages from 4 to 12 the removal of the astragalus alone is sufficient

An analysis of the cases collected by Chauvel, however, appears to show that the removal of the astragalus alone, or of the cuboid alone, does not give, as a rule, completely satisfactory results Tibiotarsal resection, *i e*, section of the tibia, and a portion of the astragalus, gives complete correction, but an anchylosis and a stiff ankle joint follows

Cuneiform resection of the tarsus is the most popular of these operative methods and has undoubtedly given remarkably good results, in certain cases, however, the ultimate benefit was not as great as was anticipated

Whichever of these operative procedures is adopted, it must be admitted that a mutilation of the foot is unavoidable, and the question naturally arises whether too great importance has not been placed by these surgeons upon the alteration in the facets of the astragulus and too little upon the connective tissue and ligaments which hold the deformed tarsus firmly in its distortion Granting that in certain adult cases tarsotomy may be required, it is certainly asking too much of the surgical world to believe that removal of the astragalus is advisable in a child of four years of age, for the clinical facts shown by the earlier teachers, and notably, Little, Adams, Brodhurst, and in this country by Buckminster Brown, give indisputable evidence that obstinate talipes equino varus is in a very large majority of cases amenable to treatment, and that the deformity is eminently a curable one by simpler means than tarsotomy Even if the astragalus is abnormal in shape and the articular facets are not on the proper surfaces, it has been abundantly demonstrated that if the tissues are sufficiently stretched or divided on the contracted side of the foot, the foot put in a normal position and kept so a sufficient length of time, a cure will follow The chief difficulty has been in obstinate cases to stretch the contracted tissue on the concave side of the distortion In the three operations for cuneiform resection of the tarsus which the writer performed, it was apparent that unless an enormous wedge was removed from the outer and upper surface of the foot, stretching to a greater or less extent of the ligaments and connective tissue on the inner and plantar surface was necessary to bring the foot into an over corrected normal position The reports of the ultimate results of cases of tarsotomy or removal of the astragalus seem to confirm the opinion that these tissues are very important in producing club foot Acting on this belief, Dr Phelphs, of Chateaugay, has by a direct open incision on the inner and plantar surface corrected a severe case, and to forcibly stretch these tissues without division, Dr Thomas Morton, of Philadelphia (Surgical Reports Pennsylvania Hospital), mentions the use of an appliance which he terms "the club-foot stretcher" This is of use, but has the defect of relying for stretching upon straps, which are necessarily liable to slip and give In order to avoid this and to give greater precision, an instrument has been devised by which the rectification is effected by means of screw pressure directly applied, as is the case in the osteoclast

The apparatus consists—

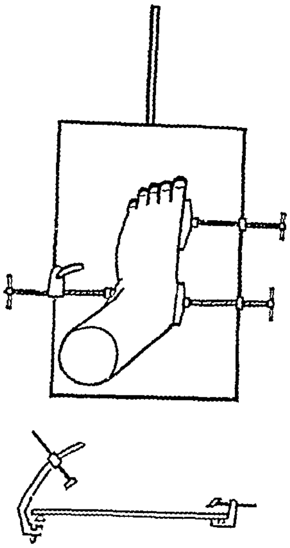

FIG 1 Cross section

(1) Of a plate large enough for any foot

(2) Of three steel buffers or padded plates which are attached at the ends to steel screw rods, playing through sockets with a female screw thread at the sides of the large plate By turning the screws, which is done by the handles, the plates or buffers are pushed forward They should be placed so as to press (1) upon the side of the first metatarsal, (2) on the side of the os calcis just beneath the inner malleolus, (3) on the outer side of the foot over the projecting head of the astragalus The female screw, through which the male screw plays, is adjustable upon an arm curved so that pressure can be applied when it may be found necessary

The sockets and arms are arranged so that they can be shifted and placed at any point along the side of the large plate, or can be shifted from side to side, so that the appliance can be used for either foot

(3) A straight rod, extended in the plane of the plate, gives increased power in raising the front of the foot This is not always needed, and can be removed

The method of operation is as follows Tenotomy is performed, and the foot rectified as far as is possible by the hand, the foot is then placed in such a position upon the plate that screw force can be applied as desired At times it will be found that fibrous tissues will be felt to tear, but ordinarily the process is a slow one, and the tissues are stretched under a constant pressure, and yield slowly The skin on the concave side of the foot will be seen to become tense as if a tear was imminent, but in the writer's experience this has not occurred and, owing to the elasticity of the skin, is hardly a probable danger The leg is to be steadied by an assistant, and the operator, turning the screws in the desired corrective, first attempts to change the varus into a valgus position without any attempt to correct the equinus deformity If the foot curls at the toes under the pressure on the side of the metatarsus, an assistant should press down upon the head of the metatarsal It will be found that the foot is firmly held to the plate when pressure is thoroughly applied, if then the plate is twisted out or up, the foot can be strained in the desired direction, the twist of the foot and the equinus position corrected In the majority of the cases upon which I have operated in this way, the foot could be brought into an over corrected position after stretching (in some cases for some minutes) A certain amount is lost in fixing the foot after the operation The fixation of the foot after operation is the most important step of all, as the ultimate success depends largely upon the position in which the foot is placed Doubtless other, and perhaps better, methods may be devised, but I have been accustomed to use a plaster bandage carefully applied over the foot, this being held by the hands in a forcibly corrected position, the bandage reaching from the toes to above the knee, the limb being slightly flexed at the knee to prevent rotation of the plaster and subsequent inversion of the foot The patient should be brought to the end of the table, an assistant should steady the knee, the foot should be grasped at the toes and ball of the foot (the fingers being on the planters and the thumb on the dorsal surface), by one hand pushing forcibly in the desired direction, counter pressure being exerted in the opposite direction by the other hand applied to the lower part of the leg The ordinary plaster roller bandage should be applied, avoiding the hands as they hold the foot, the latter exerting pressure until the plaster is sufficiently firm as not to yield when pressure is relaxed, subsequent turns of the plaster bandages can be applied to cover the gaps remaining after releasing the hold upon the foot A good deal of manual force is frequently required to hold the foot, and it is essential that the bandages should harden quickly, five minutes being ordinarily sufficient for this It is advisable to cut the bandage before it becomes thoroughly hard along the dorsum of the foot, cutting through the thickness of the plaster an oblong piece from the toes to the lower part of the leg, and nearly the width of the foot, so that if it is desirable to inspect the foot at any time, it may be done without destroying the bandage

If cut at the proper time, while the bandage is still firm enough to hold the foot, but soft enough to cut, this lid of the plaster box can be loosened without breaking or destroying the bandage If the foot or leg is protected by a layer of cotton batting, applied next the skin before the plaster bandages are put on, there is little danger of incising the skin when cutting the hardened plaster

With care in avoiding wrinkles there is little serious trouble to be anticipated from sloughs, though if much strain is put upon the foot during the fixation, sloughs on the inner side of the ball of the great toe may appear after a few days If these are troublesome, the appliance figured in the accompanying cut can be used This consists of a steel rod, bent so as to project some inches to the outer side and above the foot and along the leg, incorporated in a plaster bandage enclosing the leg and knee A buckle should be put at the lower end of this rod, into which can be fastened a piece of webbing sewn at the other end to rubber adhesive plaster wound about the foot If this causes chafing, its position on the foot can be shifted, and portions of the skin can be protected by sheet cotton Should there be a tendency for the whole bandage to slip down, adhesive plaster applied to the thigh or leg, as in extension for hip disease, with the end buckled to a buckle incorporated in the plaster bandage, will prevent this

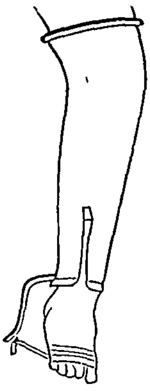

Fig 2

If it is desirable to apply a pull in other directions than that indicated in the accompanying cut, this can be done by fixing additional pieces of steel rod and applying straps to the foot in a similar way Slight œdema of the foot may occur from the absence of pressure on the foot This can be obviated by applying a cotton bandage to the foot Patients may be expected to suffer considerable pain on the first night of the application of the plaster bandage Ordinarily, this disappears in a day If one foot only is operated upon, the patient can go about immediately on crutches If both, locomotion is of course impossible

In all cases complete correction cannot be effected at one sitting, and a second or a third are sometimes necessary, though this is decidedly exceptional It is, however, important that complete correction should be brought about, that is that the whole of the sole (including the heel) should be flat on the floor when the patient stands with straight legs In most cases the foot, when released after being fixed three or four weeks in the plaster of-Paris bandage, will be found to be in the desired position if it has been properly held when the bandage is applied All that is then to be worn is an ordinary walking shoe Sometimes some constant tension is required for a few weeks This can be applied in any of the usual ways, the operation having accomplished in a few moments the stretching which otherwise would have required months or been impossible When this has been necessary in the writer's practice, the spur appliance, already figured, Fig 2, worn for a few weeks has been sufficient in all but one case (to be mentioned later) A walking appliance is to be worn by the patient for six months until the muscles controlling the motions of the foot have gained their normal balance

The oldest patient upon whom this method has been tried was 16 years of age, and subsequent experience will have to determine whether patients above this age can be treated in this way, for at this age and below it this procedure of forcible correction followed by complete fixation in a corrected position has manifest advantages over tarsotomy, in that the foot is not mutilated, and a less dangerous method is employed In comparison with the usual practice of tenotomy, followed by gradual mechanical stretching, the new method can claim in the severer and resistant cases to save a great deal of time, as will be seen in the accompanying cases And it is needless to add that mechanical stretching is much more effective than manual force applied for the same purpose

CASES

The following patients have been treated by means of mechanical forcible rectification and immediate fixation in the manner described above

Case 1 J H, boy of 5 years of age, with double congenital equina varus of the most resistant type The patient had been operated on when an infant, but insufficiently treated, with the result of a relapsed condition and two badly deformed feet Some months were spent in an unsuccessful attempt to correct the feet without operation The feet were then stretched mechanically, tenotomy having been performed, and fixed in plaster-of-paris bandages, which were worn for six weeks The patient was then fitted with a pair of walking shoes, and discharged from treatment eight weeks after the operation, except that he was directed to report for observation from time to time At the present time, two years after operation, the patient can, when standing on the heels, raise the front of the foot slightly from the floor The motions and positions and outlines of the feet are normal, and the boy walks perfectly flat upon his sole The walking shoe was discharged after being worn a year

Case 2 S W, a boy of 5 years of age, with a similar history, except that the deformity was single The foot was rectified in two months, and sent home wearing a walking shoe As he lives at a distance, he has not been seen since, but a letter from his father, January, 1884, states that he walks perfectly, and that the foot has retained its corrected position.

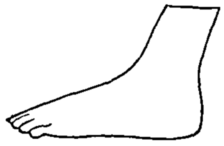

Fig 4

FROM CASTS

Case 3 A girl, 4 years of age, a similar case to the above, and the deformity corrected in the same way, and equally satisfactorily A note from the parents, January, 1884, reports that the condition of the feet remains perfectly good

Case 4 S McK, 8 years old, with a single congenital club foot of the firm type Operation and treatment the same as in the other cases Was discharged from the hospital after a stay of three months. The patient has only been seen twice in the year and a half since her discharge At the end of that time the foot was found in a normal condition, the amount of motion at the ankle being more than in any of the other cases, and indicated in the accompanying tracing, taken on a piece of paper against the leg, the sole of the foot being kept perfectly flat upon the floor

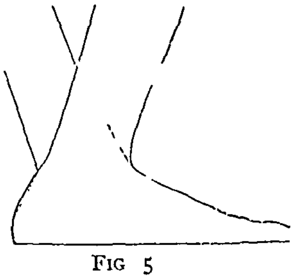

Fig 5

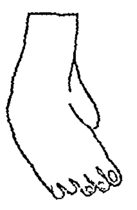

FIG 6
Drawn from cast, August, 1883

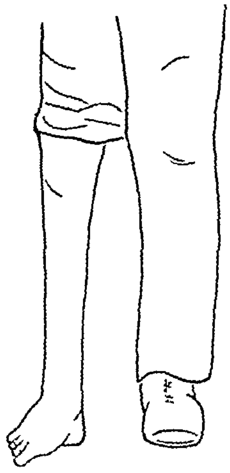

FIG 7
From photograph January 1, 1884

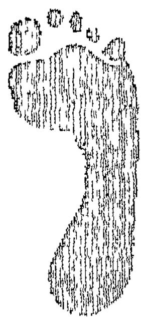

FIG 8
From imprint of sole of foot January 1 1884

CASE 5 E S , 15 years old, with a single congenital club foot of the most resistant type The patient was operated upon in the way described at one sitting A plaster bandage was applied and worn o days, some sloughs appeared, and the spur appliance put on and worn 4 weeks A walking shoe was then applied, and the patient discharged from hospital treatment, using, however, crutches in walking on account of tenderness of foot By a month, however, the crutches were discarded At the present time, April, 1884, he serves as an errand boy and is able to walk about any ordinary distance, the foot remaining as indicated in the above cut Since his discharge from the hospital the patient has been seen but six times in 6 months, and has taken care of his foot himself He prefers to wear at present his "walking appliance," a light ankle support The amount of dorsal flexion in this case is not greater than to right ankle with the leg

CASE 6 M McD , a boy 8 years old, single congenital club foot Treated as the preceding one and with a similar result Six months has elapsed since the operation and the foot is in normal position and usefulness, but the patient wears his appliance as a matter of precaution

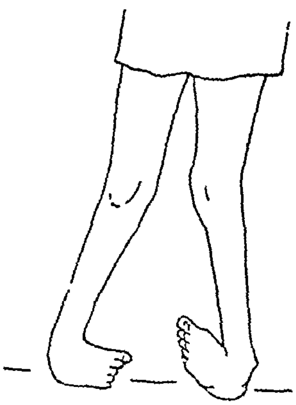

FIG 9
From photograph September, 1883

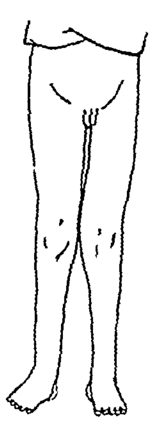

FIG 10
From photograph, January 1 1884

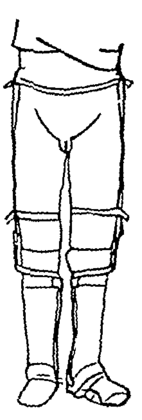

FIG 11
From photograph, January 1, 1884
Wearing appliance

CASE 7 F D , 5 years of age, with a double congenital deformity of resistant type The right foot was corrected at one sitting, but three sittings were required to bring the left foot into the position indicated in the cut, which is not perfectly normal The appliance is needed now (April 1884) upon the right foot, but further traction upon the right or another operation is required

CASE 8 M , girl 10 years of age, with a double congenital resistant club foot, which had twice undergone tenotomy with only partial success Walking shoes were applied 3 weeks after operation, and at the present time, 6 weeks later, the patient walks about freely, with the feet in a normal position Dorsal flexion at the ankle joint, however, is limited at a right angle with the leg

---

THE APPLICATION OF THE LAW OF EVOLUTION IN THE STUDY OF PATHOLOGY

BY A S V MANSFELDE, M D , ASHLAND, NEB

Introductory lecture, to the course on General Pathology and Histology in the Omaha Medical College, October 7 1884

If you join me in the belief that progress would be more rapid in the ratio in which thinkers and writers avoid ambiguous terms, you will readily find an excuse for this lengthy and I hope not altogether barren introduction to the chapter which we will now consider, or, better, a few pages of the same

The application of the law of Evolution to the study of Pathology[1] For the sake of brevity, we will take it for granted that you are fully cognizant of the work of Stricker in Germany, Klein in England, of the host who have preceded them, and of the many scholars who are coworkers with them to day upon the field of Histology You admit that they have established as a truism the assertion *omne vivum e cellulis* You grant that, from the simple non-nucleated piece of protoplasm, the monera, as an effect of the forces above enumerated, in the course of time, a nucleated amœba arose with or without its enveloping membrane—forming, in the first place, the archetype of the plant, and, in the latter, the primeval ancestor of the animal Now the mammal ovum is just such an amœba, which when joined with the male sexual element, lower by far then in its development, gives rise to a community of amœbæ cells equal in dignity (synamœbæ) by a simple division of the compound cell into equal parts Soon, however, a division of labor ensues and the peripheral layer of cells throws out innumerable protoplasm arms—ciliæ—for the prehension of food and of movement,—the first attempt at polymorphismus, which afterward attains such high and complex development These ciliated synamœbæ, or *planulata*,

---

NOTE —We received this address soon after it was delivered, but our pages were then crowded with the papers that had been read in the Sections of the American Medical Association, and we felt compelled to place it on file for use at a more convenient season The introductory part of the address is lengthy embracing a general review of the doctrine of Evolution and comments on leading evolutionists which we think less adapted to our pages than to the audience the author was addressing We therefore give only that part of the address relating directly to the application of the law of evolution to the study of Pathology —ED

very soon differentiate and form rudimentary alimentary canals, by saculation of their protoplasm bodies, retaining upon their surface, as well as in the cul de sac, the ciliæ—thus furnishing the progenitor of the host of *infusoria* still existing Their descendants, more highly differentiated and perpetuated in the *turbellaria* of to day, possess the first rudiments of a nervous system, the first ciliated cylinder epithelium, in the more complex canalization of their interior, to which finally rudiments of sexual organs are added (hermaphrodism) Soon, however, we meet with a class of animals which, in their maturity, declare themselves of nearest kinship to those just spoken of, the ascidia, or sea-squirt, a sacklike (*himatega*) body, composed of cellulose (which by biological right belongs to its vegetable cousin only), with a nerve-mass called by courtesy the brain, and which serves to regulate the few acts that mark the placid and rooted existence of the race Yet an examination of the larvæ of the ascidia reveals the wonder (it is true in its simplest form) of the first appearance of the spinal column and a spinal cord, the *noto chord* (?) forehadowing the coming race of vertebrates This embryo form of the ascidian, bereft in its maturity of sense-organs and nervous cord, equals that of the little headless fish, the *amphioxus lanceolatus*, which retains its primitive spinal cord and transmits it to its offspring,—the only living link between the world of vertebrates and the worms of the earth The embryo of the sea squirt furnishes the timber for the bridge from the latter to the former, the mature lancelet maintains the structure for mutual intercourse of the two branches of the animal kingdom

I have attempted to outline with as few words as possible the evolutional movement of protoplasm toward its highest development, the vertebrate animal The paleontologist, the comparative anatomist, the embryologist, each one for himself asserts the correctness of this genealogical table for every one member of the animal kingdom The paleontologist produces petrefactions which dug from the bowels of the earth, appear as witnesses to the living truths contained in his "sermon of the stones" The comparative anatomist proclaims aloud the identity of the plan of structure for all living things, and the embryologist, tracing with untiring zeal the development of the ovum into the mature being of its kind, declares without hesitation the repetition in the several stages of foetal development of the types of all its kindred, lower in the scale of evolution all the way down to the lump of protoplasm The dominion of the forces controlling and modeling organic forms is everywhere manifest "Capricious intrusion of a supernatural agency never occurs" All observation and all investigation point with unerring precision to the irresistible conclusion that man himself must be enrolled in this grand chain, as the last link, forged by the same forces, which called into existence the first one, the primogenital monera

Grant him, proud being which he is, the feeling that as the omega of evolution he crowns the magnificent structure, but admit, without deterioration of his place in nature, that the forces which have placed him there did achieve their triumph by a fight for the survival of the fittest, which admitted of no mercy and no preference The survivors remained to testify to the beneficence and correctness of the laws of evolution, and the dead admit the eternal fitness of things

The physiologist, in his investigations of the functions of the different organs of the body, which functions, when properly performed, lead him to regard the organism as healthy, has long since admitted that no proper standard exists by which he may adjudge the being healthy He has accepted, and that arbitrarily and simply upon his convictions, that a performance of the functions of organs, which produce harmony among the organs themselves, and comfort and longevity to the possessor, proclaims that being healthy The physiologist, therefore, has an ideal of health for each organ and tissue, the sum total of which furnishes him his ideal of a healthy animal Any deviation from this arbitrary standard of a retrogressive character leads him to turn the subject over to the pathologist with the remark that the vitiated function implies a deteriority of the being as compared with its highest level of evolution The pathologist accepts the charge, and at once sets out to search for changes in the body, guided by the manifestations of organic activity, as modified by the deteriority, *and these manifestations* are not those of the cells and tissues so changed, but of these and also those which remain healthy, or of the latter alone, but seldom, if ever, of the former exclusively Thus, the heart of a healthy adult averages ten ounces in weight, its contractions in quantity and quality are normal, as indicated by the pulse and instruments for measurement Its functions justify the conclusion that an harmonious relation exists between it and its sister organs, between the several tissues which compose it and the component parts, the cells, of each tissue itself But suppose the nutrition of the heart is modified, which, as you know, can be accomplished in many ways, and as a legitimate result some of its muscle cells degenerate fatty degeneration, the offspring of deteriorated nutrition, terminates the life and existence of a number of cells

Now a feeble, easily compressed pulse manifests itself—the veins of the lower extremities are passively hyperæmic, the vessels of the brain anæmic, the former accompanied by slowly healing ulcers, the latter by headache and spells of fainting Digestion is feeble, the mind sluggish in action, everything betokens lessened activity,—but is this the picture presented by the cells, which are fattily degenerated? They are dead, or dying, undergoing dissolution, perhaps submitting to purely mechanical changes of the chemical variety I say "perhaps," because it may be otherwise—the free cells of the connective tissue of the heart, the white blood corpuscles and lymphoid cells may, as a recent author asserts, devour the cells which, weakened by starvation, no longer resist the greedy scavengers of the body To the contrary, the whole picture, the symptomatology of fatty degeneration of the heart is exhibited by the muscle-cells still saved to the organ, and not yet touched by the causes which affected and destroyed the former The cells still existing suffice to exhibit the functions peculiar to the heart, yet upon a far lower level of evolution than was manifested by the organ prior to the degeneration of some of its colony of cells, and this lower level of evolution is also shared by all the organs which, by division of labor, stand in any relation to the heart, and this being true for every organ and every tissue of the body, the whole being is reduced to a lower level of evolution,—a level which in no wise furnishes the requisites of success in the fight for existence The being thus lowered can lead the life of a human parasite for some time, but when compelled to join the multitude in the race for life, will soon finish his earthly career But immaterial whether the course of life be rapid or slow, up to the ideal of the physiologist, or down to the limits which the pathologist declares compatible with existence, the structure of organs is the same in health and disease, the functions likewise are the same in *kind* as those of health "Virchow considers disease processes as being healthy processes occurring at the *wrong time* or at the *wrong place* * * * Disease processes are usually characterized by an *excess* or *deficiency*, as compared with the normal" We may therefore with propriety say "that disease is a deviation from health, and that this deviation consists, for the most part, in an excess or deficiency, or a perversion as to time and place"

Based upon these facts a recent author declares that remedies can only exert beneficial action when they *retard* or *hasten* function (Bartholow) We can heartily concur in this declaration, only adding that they may also influence function as to the *place* of occurrence

It will thus be seen that the forces which have created man are in no wise concerned in the necrobiosis of the cells of his tissues—the death of his organs, or of himself These forces come into play only when man strives to maintain his place in the world against his fellow, or against the odds presented by his environment It is the relation of organ to organ and being to being which offers through the forces of evolution the means for survival or of extinction Thus six-fingered ancestors are very apt to transmit to their descendants the same number of digits, opening thereby avenues for the invention of new instruments for six-fingered people, and in consequence means through which, in a fight for existence, the six fingered man might supplant his five-fingered cousin (Continuous transmission)

Again, every physician knows that tubercle may remain latent in one generation to present all its horrors in the next The lesson is plain Cousins, whose parents succumbed to tubercles, though they themselves present no marked characteristics of the malady, should never marry, because their offspring, in all likelihood, will fall an easy pray to the dread disease (Interrupted or latent transmission)

The annals of obstetric practice furnish many data showing that fathers will transmit to their sons great fecundity The same may be said of the mothers as influencing their daughters Sterility obeys the same law for both sexes The transmission of the capacity for plural births, both of males to males and females to females, belongs here (Sexual transmission)

We have also long since observed and put into everyday practice, purposely, in the breeding of our domestic animals, and instinctively in the intermarriage of human beings, the law by the workings of which peculiarities of both the parents are transmitted to the offspring — in man often to the detriment of his descendants, for an example, the intermarriage of deaf mutes, which causes the multiplication of these unfortunates to an alarming extent, sufficiently so to ask for legislation to prevent the marriage of such people (Mixed or mutual sexual transmission)

There are very few persons who, at the age of maturity, have not observed, or at least heard of, that dreaded disease, syphilis, acquired by the parent innocently or otherwise, of which it may truly be said, "it visits the children to the third and fourth generation (Transmission of acquired characteristics)

I have picked a few data from the experience of every physician to show that the laws of inheritance, as applied to man, may, under circumstances, influence his body, so that he is reduced to a lower level of evolution—a fit subject for the consideration of the pathologist, and, indeed, every thoughtful practitioner I will not tire you with instances wherein the laws of adaptation play the role of reducing the capacity for existence, in like manner as the laws of transmission, for who has not observed the deadly influence of the malaria-breeding swamp as a residence, earth and air and water furnish conditions detrimental to health and life

Can the physician, who fails to comprehend the value of a correct understanding of all these things, can he successfully combat disease, will he be a competent guide to health and happiness and threescore years and ten?

Students, if my effort has succeeded in making your head ache in the contemplation of what you ought to know as physicians, I have achieved success Your teachers, myself included, are like the quack who asserted that he caused a change into rheumatism of all the diseases of which his patrons were possessed, because he was "death on rheumatism" *We hope to be death on the headaches produced by earnest inquiry!*

To you, my fellows in the profession, who by personal experience can appreciate the difficulties which must beset every student who attempts to study pathology, that part of the *science* of medicine which actually demands a thorough knowledge of biology in its widest sense, I appeal for corroboration of the assertion, that of all the branches of medicine which it has been your fortune to study, *none* has been so important to you, after you entered upon your professional career, as a thorough knowledge of pathology

And to all of you who may not have found time to make careful inquiry of the influence which the theory of evolution possesses in the study and practice of medicine, and therefore have ignored or neglected it, I say "Do not reject it! There is no thought of modern times that more magnifies the unutterable glory of Almighty God! Remember, I beseech you, what was said by one of old times

very soon differentiate and form rudimentary alimentary canals, by saculation of their protoplasm bodies, retaining upon their surface, as well as in the cul de sac, the ciliæ—thus furnishing the progenitor of the host of *infusoria* still existing Their descendants, more highly differentiated and perpetuated in the *turbellaria* of to day, possess the first rudiments of a nervous system, the first ciliated cylinder epithelium, in the more complex canalization of their interior, to which finally rudiments of sexual organs are added (hermaphrodism) Soon, however, we meet with a class of animals which, in their maturity, declare themselves of nearest kinship to those just spoken of, the ascidia, or sea-squirt, a sacklike (*himatega*) body, composed of cellulose (which by biological right belongs to its vegetable cousin only), with a nerve-mass called by courtesy the brain, and which serves to regulate the few acts that mark the placid and rooted existence of the race Yet an examination of the larvæ of the ascidia reveals the wonder (it is true in its simplest form) of the first appearance of the spinal column and a spinal cord, the *noto chord* (?) forehadowing the coming race of vertebrates This embryo form of the ascidian, bereft in its maturity of sense-organs and nervous cord, equals that of the little headless fish, the *amphioxus lanceolatus*, which retains its primitive spinal cord and transmits it to its offspring,—the only living link between the world of vertebrates and the worms of the earth The embryo of the sea squirt furnishes the timber for the bridge from the latter to the former, the mature lancelet maintains the structure for mutual intercourse of the two branches of the animal kingdom

I have attempted to outline with as few words as possible the evolutional movement of protoplasm toward its highest development, the vertebrate animal The paleontologist, the comparative anatomist, the embryologist, each one for himself asserts the correctness of this genealogical table for every one member of the animal kingdom The paleontologist produces petrefactions which, dug from the bowels of the earth, appear as witnesses to the living truths contained in his "sermon of the stones" The comparative anatomist proclaims aloud the identity of the plan of structure for all living things, and the embryologist, tracing with untiring zeal the development of the ovum into the mature being of its kind, declares without hesitation the repetition in the several stages of foetal development of the types of all its kindred, lower in the scale of evolution all the way down to the lump of protoplasm The dominion of the forces controlling and modeling organic forms is everywhere manifest "Capricious intrusion of a supernatural agency never occurs" All observation and all investigation point with unerring precision to the irresistible conclusion that man himself must be enrolled in this grand chain, as the last link, forged by the same forces, which called into existence the first one, the primogenital monera

Grant him, proud being which he is, the feeling that as the omega of evolution he crowns the magnificent structure, but admit, without deterioration of his place in nature, that the forces which have placed him there did achieve their triumph by a fight for the survival of the fittest, which admitted of no mercy and no preference The survivors remained to testify to the beneficence and correctness of the laws of evolution, and the dead admit the eternal fitness of things

The physiologist, in his investigations of the functions of the different organs of the body, which functions, when properly performed, lead him to regard the organism as healthy, has long since admitted that no proper standard exists by which he may adjudge the being healthy He has accepted, and that arbitrarily and simply upon his convictions, that a performance of the functions of organs, which produce harmony among the organs themselves, and comfort and longevity to the possessor, proclaims that being healthy The physiologist, therefore, has an ideal of health for each organ and tissue, the sum total of which furnishes him his ideal of a healthy animal Any deviation from this arbitrary standard of a retrogressive character leads him to turn the subject over to the pathologist with the remark that the vitiated function implies a deteriority of the being as compared with its highest level of evolution The pathologist accepts the charge, and at once sets out to search for changes in the body, guided by the manifestations of organic activity, as modified by the deteriority, *and these manifestations* are not those of the cells and tissues so changed, but of these and also those which remain healthy, or of the latter alone, but seldom, if ever, of the former exclusively Thus, the heart of a healthy adult averages ten ounces in weight, its contractions in quantity and quality are normal, as indicated by the pulse and instruments for measurement Its functions justify the conclusion that an harmonious relation exists between it and its sister organs, between the several tissues which compose it and the component parts, the cells, of each tissue itself But suppose the nutrition of the heart is modified, which, as you know, can be accomplished in many ways, and as a legitimate result some of its muscle cells degenerate fatty degeneration, the offspring of deteriorated nutrition, terminates the life and existence of a number of cells

Now a feeble, easily compressed pulse manifests itself—the veins of the lower extremities are passively hyperæmic, the vessels of the brain anæmic, the former accompanied by slowly healing ulcers, the latter by headache and spells of fainting Digestion is feeble, the mind sluggish in action, everything betokens lessened activity,—but is this the picture presented by the cells, which are fattily degenerated? They are dead, or dying, undergoing dissolution, perhaps submitting to purely mechanical changes of the chemical variety I say "perhaps," because it may be otherwise—the free cells of the connective tissue of the heart, the white blood corpuscles and lymphoid cells may, as a recent author asserts, devour the cells which, weakened by starvation, no longer resist the greedy scavengers of the body To the contrary, the whole picture, the symptomatology of fatty degeneration of the heart is exhibited by the muscle cells still saved to the organ, and not yet touched by the causes which affected and destroyed the former The cells still existing suffice to exhibit the functions peculiar to the heart, yet upon a far lower level of evolution than was manifested by the organ prior to the degeneration of some of its colony of cells, and this lower level of evolution is also shared by all the organs which, by division of labor, stand in any relation to the heart, and this being true for every organ and every tissue of the body, the whole being is reduced to a lower level of evolution,—a level which in no wise furnishes the requisites of success in the fight for existence. The being thus lowered can lead the life of a human parasite for some time, but when compelled to join the multitude in the race for life, will soon finish his earthly career. But immaterial whether the course of life be rapid or slow, up to the ideal of the physiologist, or down to the limits which the pathologist declares compatible with existence, the structure of organs is the same in health and disease, the functions likewise are the same in *kind* as those of health. "Virchow considers disease processes as being healthy processes occurring at the *wrong time* or at the *wrong place*. * * * Disease processes are usually characterized by an *excess* or *deficiency*, as compared with the normal." We may therefore with propriety say "that disease is a deviation from health, and that this deviation consists, for the most part, in an excess or deficiency, or a perversion as to time and place."

Based upon these facts a recent author declares that remedies can only exert beneficial action when they *retard* or *hasten* function (Bartholow). We can heartily concur in this declaration, only adding that they may also influence function as to the *place* of occurrence.

It will thus be seen that the forces which have created man are in no wise concerned in the necrobiosis of the cells of his tissues—the death of his organs, or of himself. These forces come into play only when man strives to maintain his place in the world against his fellow, or against the odds presented by his environment. It is the relation of organ to organ and being to being which offers through the forces of evolution the means for survival or of extinction. Thus six-fingered ancestors are very apt to transmit to their descendants the same number of digits, opening thereby avenues for the invention of new instruments for six-fingered people, and in consequence means through which, in a fight for existence, the six fingered man might supplant his five fingered cousin. (Continuous transmission.)

Again, every physician knows that tubercle may remain latent in one generation to present all its horrors in the next. The lesson is plain. Cousins, whose parents succumbed to tubercles, though they themselves present no marked characteristics of the malady, should never marry, because their offspring, in all likelihood, will fall an easy pray to the dread disease. (Interrupted or latent transmission.)

The annals of obstetric practice furnish many data showing that fathers will transmit to their sons great fecundity. The same may be said of the mothers as influencing their daughters. Sterility obeys the same law for both sexes. The transmission of the capacity for plural births, both of males to males and females to females, belongs here. (Sexual transmission.)

We have also long since observed and put into everyday practice, purposely, in the breeding of our domestic animals, and instinctively in the intermarriage of human beings, the law by the workings of which peculiarities of both the parents are transmitted to the offspring — in man often to the detriment of his descendants, for an example, the intermarriage of deaf mutes, which causes the multiplication of these unfortunates to an alarming extent, sufficiently so to ask for legislation to prevent the marriage of such people. (Mixed or mutual sexual transmission.)

There are very few persons who, at the age of maturity, have not observed, or at least heard of, that dreaded disease, syphilis, acquired by the parent innocently or otherwise, of which it may truly be said, "it visits the children to the third and fourth generation." (Transmission of acquired characteristics.)

I have picked a few data from the experience of every physician to show that the laws of inheritance, as applied to man, may, under circumstances, influence his body, so that he is reduced to a lower level of evolution—a fit subject for the consideration of the pathologist, and, indeed, every thoughtful practitioner. I will not tire you with instances wherein the laws of adaptation play the role of reducing the capacity for existence, in like manner as the laws of transmission, for who has not observed the deadly influence of the malaria-breeding swamp as a residence, earth and air and water furnish conditions detrimental to health and life.

Can the physician, who fails to comprehend the value of a correct understanding of all these things, can he successfully combat disease, will he be a competent guide to health and happiness and threescore years and ten?

Students, if my effort has succeeded in making your head ache in the contemplation of what you ought to know as physicians, I have achieved success. 'Ye men of Israel, take heed to yourselves, what ye intend to do And now I say unto you, if this counsel be of men it will come to naught, but if it be of God ye cannot overthrow it, lest haply ye be found fighting against God ' Shall I continue the quotation ?—'and to Him they all agreed ' "

JABORANDI AS A GALACTAGOGUE

BY CHARLES WESLEY ROOK, M D, QUINCY, ILL

Gentlemen of the Adams County, Ill , Medical Society Permit me to again direct your attention for a few moments to the medicinal agent, jaborandi In an article read in your presence, February 11, 1884, and published in the St Louis *Medical and Surgical Journal,* April, 1884, I gave some of my experience with jaborandi In that paper was reported a case illustrating the galactagogue action of this agent

The case reported is briefly this

"Mrs J B S , A primipara, confined January 1, 1884 Labor natural and comparatively easy, child, female, average size and well developed As the breasts secreted no milk the child was artificially nourished for a few days The mother and child progressed well until January 6, when I was hastily summoned, and found Mrs S suffering severely from headache, high fever, the surface of the body being hot and dry, pulse 130 per minute, and her breasts more tense and painful than they had yet been Not having with me anything that would give her relief more quickly, or better meet the indications present than the extractum pilocarpi fluidum, she was given a ♏xij dose, with directions for its repetition every half hour, until free diaphoresis was induced The desired effect followed the third dose

Simultaneously with the appearance of the perspiration and the increased flow of saliva, the milk began flowing in a stream from the left breast, and so continued during the active stage of diaphoresis On the following day, while the skin was yet moist from the jaborandi received the evening previous, milk began flowing from the right breast "

At no subsequent period has that little child lacked nourishment In the discussion following the reading of my paper, with reference to the case just mentioned, this question was asked "Don't you think that the milk was just about ready to be secreted, and that its secretion would have occurred soon without the use of jaborandi ?" I answered "That, as the secretion was not established before, and occurring in such abundance upon the exhibition of jaborandi, I naturally attributed this sudden increase of functional activity to the jaborandi "

Since then, I have administered jaborandi in four cases in which there was a deficiency of milk secreted, with the intention of increasing the supply, and with results, in each case, nearly as marked as in the one reported It is to neither of these cases that I ask your attention, but to another case in which I claim strong circumstantial evidence, if not proof positive, concerning the galactagogue action of jaborandi

Mrs L S M , who is in feeble health, weighing less than 110 pounds, is thirty eight years of age, been married fifteen years, and has given birth to nine children, five of whom are now living Mrs M furnished an abundance of milk for the nourishment of her first child, but on account of a failure of her supply of milk, the cause of which I could not learn, she was not able to nurse either of her next seven children, which in lieu of their mother's breast received the bottle Of the seven there yet remaineth three little pale-faced children as living witnesses to the preservative power of the bottle

January 3, 1885, I was called to see Mrs M On my arrival I found the labor just completed An average-sized male child was born, and being yet attached to the cord, the latter was severed, and the mother and child made as comfortable as possible Inquiry concerning the condition of the breasts was made, when the history as above noted was elicited On physical examination of the mammary glands, no signs of functional activity could be observed within them Directions were accordingly given for the artificial feeding of the child I then told Mrs M that if her milk did not appear within a few days I would give her some medicine which would cause the secretion of milk in abundance Three days after confinement, the mammary glands yet remaining inactive, she was ordered ♏xxx doses of ext jaborandi fl every half hour, until free perspiration and salivation were produced These effects were attained upon the exhibition of the fifth dose The only noticeable effect upon the mammary glands was a slight enlargement My patient, being very weak, was allowed an interval of one day in which to somewhat recover from the depressing effect of the free diaphoresis, then, as the condition of the mammary glands remained unchanged, she was given four ♏xxx doses at intervals of one-half hour, when the usual effect upon the skin and salivary glands was produced, while the following effect upon the mammary glands was noted On this second exhibition of jaborandi the breasts rapidly filled, becoming tense and painful, but the pain and tension were soon relieved by the free flow of milk from each breast

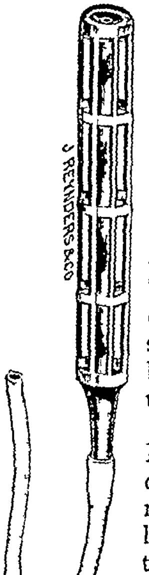
Here ended, for the present, any further necessity of artificially feeding the child

Three weeks later I was called to see the child, and was informed that more milk was secreted than the child could nurse, the excess flowing freely from her breast One week later I called in order to obtain a later report for my paper, and was surprised to find that the milk supply had failed and that the child was again nursing the bottle I also learned that my patient had had, ever since the first appearance of the milk, a great fear that the supply would soon be exhausted, and wanting to do what she could to continue the secretion, had taken from the commencement, and without my advice, a daily ♏xxx dose of ext jaborandi fl The drug was ordered discontinued for two days, at which time, the mammary glands exhibiting no signs of their former activity, she was given three ♏xxx doses of ext joborandi fl , at intervals of half an hour, which produced free perspiration, salivation, lachrymation, enuresis, and, as we had hoped, a free lacteal discharge from each breast The further use of the drug is forbidden Nearly two weeks have elapsed since the last exhibition of ext jaborandi fl , and my patient is secreting an abundance of milk From my own experience with this medicinal agent, I am convinced that, in addition to the properties which make it a valuable diaphoretic, jaborandi has, first, a special stimulating effect upon the mammary secretions, second, the continued *exhibition of the agent will be followed by functional exhaustion of the mammary glands,* and third, a functionally exhausted mammary gland may, after an interval of rest, be again stimulated to activity by the proper exhibition of jaborandi

Feb 17th, 1885

COMBINED RECTAL AND INTRA-UTERINE IRRIGATOR

BY JNO S COLEMAN, M D , AUGUSTA, GA



In the *Medical Record* of New York for May 10, 1879, I presented to the medical profession the *Metro Clyst* I now desire to call attention to a modification of this instrument which makes it available for the diseases of the rectum and surrounding pelvic structures The instrument was skillfully constructed for me in April of last year by Messrs Reynders & Co , of New York city It is of hard rubber, and consists of a cylindrical frame or cage traversed by a central tube This arrangement insures the easy exit of the injected fluid Any ordinary syringe can, by means of rubber tubing, be attached to it My preference in the use of hot water is for the syphon

Thanks to the genius of Dr T A Emmet, we all now appreciate the indispensable value of hot water in inflammation and as a hæmostatic Though I have not yet had an opportunity of testing the merits of this instrument in pelvic cellulitis or peritonitis, I feel confident that we will find it one of our most efficient measures in combating these serious and obstinate forms of disease So far as I am informed, Dr J R Chadwick was the first to advocate the rectal use of hot water in the treatment of pelvic inflammations (*Vide* his able and interesting paper in the Transactions of the American Gynæcological Society for 1880) To me it promises much in acute prostatitis, rectitis, and internal hæmorrhoidal troubles

I have had most gratifying success from its use in a case of puerperal endo metritis, and in one of rectal ulcers

Apomorphine in Asthma —Dr Weber, of Darmstadt, has used apomorphine, in doses of one-twelfth of a grain three times a day, in chronic asthma, with success —*Chi Med Journal*

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS.

Practical Remarks on the Use of Electricity in Mental Disease

Dr A DeWatteville writes, in *The Journal of Mental Science,* very encouragingly on the benefits of this treatment in mental disease, and considers the following as the chief indications to govern its use

First—To promote the equilibrium of the cerebral innervation by acting directly on the nutrition of those centers which are deficient, functionally or organically, through molecular, vaso-motor or other influences Experience shows we can do this, in some cases, by direct galvanization of the head and neck

Second—To rouse up the peripheral and spinal innervation, and to indirectly restore their necessary equilibrium by supplying a deficiency in the different influxes upon which it partly depends Here galvanization of the spine, and general faradisation (with the moist electrode or wire brush, according to the requirements of the case) will be of service

Third—When the cerebral troubles are connected with some disturbance of the abdominal or pelvic viscera (visceral parœstheriæ, torpidity, and the like) to correct or mitigate the latter by the application of either current, or, better still, by galvano faradisation The value of electricity in visceral neurosis is very great, though hitherto unrecognized

Fourth—To relieve certain symptoms as they arise according to the rules laid down in the usual treatises It must not be forgotten, for instance, that general faradisation is a good tonic and excitant of general nutrition In some cases, again, appropriate electrization acts as a promoter of sleep

Meat Preparations —Dr Stutzer, Director of the Imperial Agricultural Chemical Laboratory, Bonn, Rhenish Prussia, has been, for several years (*Midland Medical Miscellany*), testing articles of food introduced into Germany for the use of invalids and children In the tests applied to meat preparations, he first established the percentage of organic ingredients, mineral ingredients (salt) and water, and secondly, he tried, as far as feasible, to decompose the organic principles in them, determining, for instance, what proportion of nitrogen must be credited to the easily digested albumen and to peptone , and thus estimated, in the usual way, by multiplying by 6 25 (assuming that the constituent principles contained, on an average, 16 per cent of nitrogen) the quantity of albumen and peptones As certain of the preparations contained no albuminous principles (fibrine) that were soluble in water, with these it became necessary to ascertain, by means of an additional digesting experiment, how much of the albuminous principles can be digested Next, he took into consideration the quantity of nitrogen present in the form of meat bases (such as creatine, camine, etc), because these meat bases, together with potash and phosphoric acid, possess a very high importance as relishing and stimulating means for the nervous system The analysis of the mineral components went to the determination of phosphoric acid, potash and chlorine

The most nourishing of the preparations analyzed proved to be Carnrick's beef peptonoids, as in this preparation there was in 100 parts (by weight) as much peptone and readily digestible albumen as there were in

178 parts (by weight) of Johnston's Fluid Beef,
285 parts (by weight) of Kemerich's Extract of Beef,
483 parts (by weight) of Murdock's Liquid Food,
765 parts (by weight) of Brand & Co's Essence of Beef,
784 parts (by weight) of Lawry & Moore's Fluid Meat,
898 parts (by weight) of Liebig's Extract of Beef,
902 parts (by weight) of Benzer's Peptonized Beef Jelly

Carnrick's Beef Peptonoids present another distinguishing mark, as containing a not inconsiderable quantity of heat-producing and albumer-economizing elements, viz 10 67 per cent fat and 10 02 per cent of soluble non-nitrogenized substances, such as dextrine and sugar From this standpoint, Liebig's extract of meat, a favorite though it be, must be relegated to a subordinate rank, and it will thus be seen that, as for that matter, the makers themselves admit it is not an article of food, but a stimulant or appetizer, in consequence of its high percentage of meat bases (creatine, etc), and phosphate of potash, in which respect it surpasses other preparations

But he arrives at very different numerical ratios of proportion by comparing the percentages of nitrogen recurring in the form of meat bases in these preparations He excludes from his table Carnirck's beef peptonoids, which contain but a slight proportion of these elements, and also Lawry & Moore's fluid meat, which latter contains, in addition to the meat bases, other unknown nitrogenized combinations, and therefore a comparison of the fluid meat with the other preparations would be inadmissible

One hundred parts (by weight) of Liebig's extract of meat contain the same quantity of nitrogen in the form of meat bases, in

126 parts (by weight) of Kemmerich's Extract of Beef,
558 parts (by weight) of Johnston's Fluid Beef,
1,844 parts (by weight) of Benzer's Peptonoid Beef Jelly,
4,161 parts (by weight) of Murdock's Liquid Food,
5,053 parts (by weight) of Brand's Essence of Beef

If a medical man desires to give an invalid or convalescent a preparation, by the use of which the formation of flesh and blood is to be promoted, and vigor infused into a patient, it will be his duty to examine into the proportions of easily digested albumen and peptones contained in any particular food preparation, and in this respect, as may be seen from the foregoing table, Carnrick's Beef Peptonoids stands first and foremost among the preparations examined

MEDICINE.

CLINICAL OBSERVATIONS ON THE BLOOD OF THE INSANE —Dr S Rutherford Macphail, in *The Journal of Mental Science,* gives this summary of an interesting and extended article

1 While there is no evidence to show that anæmia in itself is a cause of insanity, yet an anæmic condition of the blood is undoubtedly in many cases intimately associated with mental disease

2 The blood in the demented class of asylum patients is deficient in hæmoglobin and in hæmacytes, and the deterioration progresses as age advances

3 The blood in patients known to be addicted to masturbation is deteriorated in a marked degree

4 The blood is below the normal standard in general paralysis, and the deficiency is greater in the active and completely paralyzed stages of the disease than in the intervening periods of inactivity and quiescence

5 While there is a deficiency in the quality of the blood in epileptics, the decrease is not so pronounced as in ordinary dements at the same age

6 Prolonged and continuous doses of bromide of potassium do not cause deterioration in the quality of the blood

7 Prolonged attacks of excitement have a deteriorating influence on the quantity of the blood

8 The blood of the average number of patients on admission is considerably below the normal standard

9 In patients who recover, the quality of their blood improves during residence in the asylum, and on discharge is not much below the normal standard

10 There appears to be a close connection between gain in weight, improvement in the quality of the blood, and mental recovery

11 While there is a definite improvement in the condition of the blood during mental convalescence in all cases, the improvement is both more pronounced and more rapid in those who have had tonic treatment

12 The four tonics which, either alone or in combination, proved most efficacious in restoring the quality of the blood, as shown by these observations, may be classed in order of value thus (*a*) iron, quinine and strychnia, (*b*) iron and quinine, (*c*) iron alone, (*d*) malt extract

13 Arsenic proved of little value as a blood tonic in these cases, and the observations with quassia and cod liver oil did not give satisfactory results

14 The close connection which exists between improvement in the quality of the blood, increase in weight, and mental recovery, the converse which exists in cases of persistent and incurable dementia, and the marked improvement which is effected by certain remedial agents—show that this line of clinical research, more especially with reference to the curative treatment of the insane, should have more attention paid to it than has hitherto been the case

THE THERAPEUTIC ACTION OF ACONITUM FEROX OR INDIAN ACONITE —Dr D. H Cullimore brings this drug to our notice in a paper read before the section of *Pharmacology* and Therapeutics of the British Medical Association, and reported in the *British Medical Journal*. The United States authorities, in common with the British and French, recognize only the aconitum napellus. The aconitum ferox sen vivosum is the most powerful and deadly of all the species of aconitia. A preparation of the root is much used in the Himalaya Mountains, where it is a native, to poison arrows. Dr Cullimore details some 13 cases in which he has used it. As an external application he thinks it distinctly superior to aconite liniment. It is more diuretic, and less diaphoretic than the aconitum napellus, and probably, also, because it is less diaphoretic it is less antipyretic. As an anæsthetic, or dysæsthetic, in gouty and rheumatic conditions, it is superior to the aconitum napellus, while, as a vascular depressant, in small doses it is not so powerful. In minute doses it probably acts as a cardiac stimulant. In small doses, it stimulates the nervous system at all parts, and peripherally. In moderate doses it causes dysæstheria, perversion of sensation, as exemplified by the tingling and numbness, while, in larger doses, it is an anæsthetic, and a paralyzer of the nerves and other centers. Its first action on the nervous system, with its diaphoretic effect, will probably be found to explain its good effect in leprosy.

Its first effect is to produce heat, followed by lowering of the temperature and cold perspiration. Its antipyretic effect is due to a lowering of the central circulation, by which it lessens the production of heat, while, by its diaphoretic action, it facilitates its removal. When given in chronic-rheumatic conditions, it may be given till tingling is produced, whereas, in acute rheumatism, its action on the heart, though useful in moderate doses in the early stages, and in small throughout, must be carefully noted later on in this disease. In still larger doses, it causes nausea and vomiting, muscular tremors of the limbs, profuse cold sweats, disappearance of the painful peripheral sensations, dryness of the throat and fauces, ardent thirst, alternations of heat and cold, great irregularity of the heart's action and of respiration, feebleness, and even loss of muscular power, great and burning heat of the stomach, throat and intestines, attended with some muscular cramp, extending to nails, lips and heart. This, if life be prolonged, is followed by inflammation, convulsions, intoxication, delirium and death, which is sometimes attended with stupor, though at others the mind remains clear to the last.

With regard to the aconitum heterophyllum, it is known in India, under the name of atees, as a powerful tonic and aphrodisiae medicine. It possesses more of the poisonous, antipyretic, or anodyne properties of the other species of aconite. Sixty grains were given to a large dog without any injurious effect. As a tonic it is useful. As an aphrodisiac, Dr Cullimore had had no personal experience, but the late king of Burmah, who kept seventy wives, and whose opinion, therefore, is deserving of respect, held it in high esteem.

ON THE NATURE OF SYMPATHETIC OPHTHALMIA.—Deutschmann, in an elaborate paper in *Græfe's Archiv*, gives (Ed MEDICAL JOURNAL), as the result of experiment and observation during the last two years, a large amount of very strong evidence in favor of the view held by Leber and others—that the transferrence of destructive inflammation from one eye to the other takes place along the optic nerves. By injecting the spores of staphylococcus pyogenes aureus into the vitreous chamber of one eye of a rabbit, on the second day there were marked hyperæmia of the disc of the other eye, and symptoms of meningitis. Microscopic post-mortem examination on the third day showed purulent infiltration of the optic nerve of the first eye, traced to the chiasm and down the nerve of the second eye to the papilla, the piamater of the base of the brain being inflamed. In all the situations involved in the infiltration, micro organisms—the same as those injected—could be found. Weak solutions of these spores produced death at longer intervals, with no symptoms of meningitis. These experiments never induced a definite iritis, probably, it was thought, because the animal died before the inflammatory action reached the more anterior portions of the eye. The direction of the lymph current in the optic nerve is from the center toward the eye, and this fact is used to explain why meningitis does not occur unless the inflammation in the first eye be extremely intense. The micro organisms, as they grow in the first eye, creep up the corresponding nerve until they reach the base of the brain, from whence they are carried by the lymph current down the opposite nerve, in that way reaching the other eye. Deutschmann made a microscopic examination of all the eyes at his disposal which had been removed on account of a sympathetic inflammation of the other eye, making use of the new methods of staining for the detection of micro organisms. In all the eyes examined, with one exception, he found distinct micro-organisms, and these, too, were always to be found in the nerve. In four fresh cases the eye on removal was soaked with boiled distilled water, then opened and a small amount of pus, in the vitreous or elsewhere, put into blood serum, and treated according to Koch's method for micro organisms. The micro-organism obtained was identical with the one before mentioned, and when injected into the vitreous of living rabbits produced the same symptoms, preparations also obtained from the blood of the animals (which as before were always found to die eventually of septicæmia) were found to be not less virulent in their action than the original preparations. One of the human eyes from which these cocci were obtained, was removed from the patient before any affection of the other eye had taken place, although there had been a possibility of sympathetic inflammation existing for four years. This fact is interesting, showing how long the micro organisms may retain their dangerous properties—the fact of these remaining dormant so long being probably due to the mass of pus from which they were taken being more or less incapsuled in the eye. In another case a portion of iris removed from the sympathetically inflamed eye furnished the same cocci The results of his investigations led him to the conclusion which he expresses as follows "I have been led by all the facts brought forward to form the opinion that in all probability the sympathetic ophthalmia met with in man is an inflammation spreading from the first to the second eye along the optic nerve, that the exciting cause is either a micro-organism, which in some manner has been introduced into the eye, or perhaps, though rarely, a chemical irritant as well"

SURGERY.

ON LIFE SAVING FROM DROWNING BY SELF-INFLATION —Dr Henry R Silvester, who is a Fothergill Medalist of the Royal Humane Society, makes the following remarkable suggestions in a recent number of the *Lancet* He has already demonstrated at the International Fisheries Exhibition the possibility of inflating the subcutaneous space in animals so as to render them sufficiently buoyant to be employed either singly or yoked together to convey persons from a wreck to the coast, and later, by means of a blow-pipe and elastic syringe, he inflated at the wrist the subcutaneous tissue of the whole body with the result that in a few minutes sufficient air passed under the skin to support a weight in water of between forty and fifty pounds This amount is considerably more than would be required to preserve a person from drowning, nine or ten pounds being considered sufficient

His proposed operation consists in making a small puncture—not larger than would allow, for instance, of the passage of an ordinary blow-pipe—in the mucous membrane of the inside of the mouth, the object being to open a communication for the passage of air from the cavity of the mouth into the subcutaneous spaces of the neck The situation chosen for the puncture is in the angle formed between the gum of the lower jaw and the side of the under lip or cheek about opposite the first molar tooth of the lower jaw The point of the instrument perforating should be passed down a short distance between the skin of the side of the face and the superficial fascia of the neck, taking care not to puncture either the skin or the superficial fascia This having been done, and the instrument removed, in order to inflate the skin of the neck and chest, the patient should close the mouth and nose, and make a succession of forcible expiratory efforts, when the air contained in the cavity of the mouth will pass freely into the subcutaneous tissue of the neck These expiratory efforts, inspiration being effected through the nostrils, should be continued until the skin is fully distended with air, which will pass readily to both sides of the neck and down the chest as far as the nipples, and this is all that is required to render the body buoyant in water Should it so happen that the superficial fascia has been punctured and the air pass beneath it, the only difference in effect would be that the extent of air would be limited by the attachments of that membrane to the clavicle below and he border of the jaw above The amount of air which the skin of the average neck is capable of holding without undue distension has been measured, and found to be enough *to support ten pounds, and this is amply* sufficient to support the body immersed in water The time required for inflation is found to be less than three minutes The neck may be kept in an inflated condition by closing the puncture by pressure on the outside of the cheek by the finger, or by keeping the mouth distended with air, and when required the air may be immediately discharged from the neck by allowing the puncture to remain open, or by suction

The advantages he sums up as follows —1 The proceeding is perfectly harmless and almost painless, quickly done, and almost immediately recovered from 2 It may be learnt in a few minutes, no technical knowledge being required, and may be accomplished by the person himself without assistance 3 No special apparatus is required In an emergency the point of a penknife, or even a sharp pointed splinter of wood, is all that would be required The inflating apparatus is the person's own lungs 4 The air could be repeatedly re inflated, and even during prolonged immersion

OBSTETRICS AND GYNÆCOLOGY.

THE TREATMENT OF THE UMBILICAL CORD —Crede and Weber (Leipzig in the *Archiv f Gynak*, *Edin Med J*) set themselves to answer the questions, How is bleeding from the divided cord to be obviated? and, How is inflammation and its results, of the fœtal portion, to be prevented? In the first place, they state that they are dissatisfied with the ordinary methods of secural by tape or linen, but both from clinical experience and as a result of experiments made on cords post partum, they recommend strongly the use of elastic ligatures, as suggested by Budin, and as used by them in Leipzig for the past eighteen months, with perfectly satisfactory results The ligature used is 2 mm thick, and is tightly wrapped round the cord, tied, and again taken half round and retied As by this means the operator can be perfectly certain that there will be no bleeding, the point ligatured should be close to the skin on the cord, as, according to the writers, the shorter the portion left attached to the child, the less chance is there of traumatic inflammation The after-treatment simply consists in keeping dry wadding round the stump, and carefully drying after the child has been bathed Since the above treatment has been followed in the Leipzig Maternity, there have been no cases of umbilical disease

STATE BOARD OF HEALTH OF WEST VIRGINIA —The vacancy in this Board caused by the resignation of Dr James E Reeves, has been filled by the appointment of Dr L D Wilson, of Wheeling, W Va, by the Governor of the State

THE
Journal of the American Medical Association.
PUBLISHED WEEKLY

The Editor of this Journal would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information, should be accompanied by the writer s full name and address although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

MEDICAL EDUCATION AND THE AMERICAN MEDICAL ASSOCIATION

Camden, N J, Feb 9, 1885

Editor Journal of the American Medical Association

Dear Doctor I have not seen any report in the Journal of the resolution on medical education offered by me and passed at the last meeting of the American Medical Association at Washington

On offering the resolution, I stated that I was impelled by the consideration of the facts that, for years past, men could graduate at our leading colleges without ever having so much as felt a man's pulse or listened to a diseased lung, that the science of medicine was the most difficult and complex of all sciences, that the proper understanding of the human system, the intricate nature of disease the difficult problems of therapeutics, really required and should receive more training for their proper understanding and application than the art of shoeing a horse or making a shoe for a human being, that the two courses of instruction of about five months each, alleged to have been given a graduate by about ninety out of one hundred American Medical Colleges, was ridiculous in the extreme, that the courts and the intelligent people of this country as well as abroad had refused to acknowledge that the diplomas of these colleges represented a proper medical education, that I had been officially informed by letter that the University of New York had to abandon the effort recently made to give a better course of instruction and go back to the ten months' course, "*because the profession would not support it*," and that the issuing annually of thousands of diplomas to young men thoroughly unprepared to assume the awful responsibilities of a physician was an outrage on the community and ruinous to the profession itself

Since last spring the subject has been extensively discussed all over the country and in the different medical journals, and the silence of our Journal has been extensively commented upon I have therefore sent you with this letter two or three marked articles, which I hope will enable you to publish a pretty fair account of that important matter as it was handled at our last meeting —Very respectfully yours,

D Benjamin

In regard to the first clause in the foregoing letter, we have only to remark, that if our correspondent has not seen any report of his resolution in the Journal, it is because he has not looked in the right place for it *If he will look over the full record of the* proceedings of the meeting in Washington, as reported officially by the Permanent Secretary, and published in the Journal for May 24, 1884 (only a little more than two weeks after the meeting was held), he will find, on page 565, of volume 2, his resolution correctly given, together with the fact of its discussion and adoption We have copied his letter here, however, more particularly for the purpose of correcting the impression apparently entertained by many, as indicated by the criticisms, or more properly the disparaging remarks, frequently heard concerning the unwillingness of the American Medical Association to allow a free discussion of the subject of medical education at its annual meetings It is proper to say that, so far as we have observed, these disparaging remarks are made either by members who have begun to take part in the doings of the Association only during the last few years or by editors of medical journals who have never taken the trouble to attend half-a-dozen meetings or even to maintain an active membership in the Association, or to make themselves acquainted in any adequate degree with the past action of the Association in regard to the important subject of the education of our profession If these zealous friends who have not yet learned that the adoption of a resolution by a society organization, declaring what *ought to be done*, is not quite equivalent to the enactment of a law by a properly constituted legislative body will take a glance over the first twenty annual volumes of Transactions, they will find in each the record of an able report from the standing committee on Medical Education, and the discussion and adoption of resolutions both numerous and explicit, sufficient, indeed, if added to the several annual reports, to make a fair sized octavo volume They will find also that the twenty years of discussions and resolves culminated, in 1866, in an earnest appeal to the medical colleges of the country to hold a delegated convention from their faculties, and agree upon a more thorough, systematic and extensive system of medical college education, which might be adopted by all the schools in concert

If they look carefully enough, they will find that in response to such appeal a very creditable college convention was held the following year in Cincinnati, presided over by that eminent scholar and professional teacher, Dr Alfred Stille, of the Medical Department of the University of Pennsylvania This convention, after a three days' session, agreed upon and recommended a system of medical college education, to be preceded by an adequate general education, as comprehensive, systematic and thorough as the most zealous of the critics of the present day would be willing to comply with This action was reported to the American Medical Association, then holding its annual meeting in the same city, and it received the prompt approval of that body (See Transactions, vol 18, page 28, 1867)

Two years later, May, 1869, another convention of delegates from medical colleges was held in Washington, presided over by no less a personage than the late Dr Samuel D Gross, of the Jefferson Medical College After a free discussion, that convention simply renewed the recommendations of the former one, and their action was again promptly endorsed by a vote of the Association, then in annual session in the same city These acts of the association, fully recommending the exaction of a fair standard of general education before commencing the study of medicine, and the study of medicine three years, embracing three consecutive graded courses of medical college instruction, with adequate hospital clinical facilities, still stand on the records unrepealed and unaltered by any subsequent action as the deliberate expression of opinion by that body It is true that only a moderate number of the medical colleges have adopted these recommendations But in this number are several of the oldest and most reliable colleges in this country

Many others, however, are making some progress in the same direction, and under the pressure of the strong public sentiment largely developed by the numerous able reports and discussions to which we have alluded, this progress will be accelerated from year to year And yet, so long as the college diploma is accepted as equivalent to a license to practice medicine and surgery, without a further and independent examination of the candidate, the temptation to make its acquirement easy and cheap as a means of increasing the number of students in any given college, will remain too strong to be successfully resisted Indeed, if all the respectable medical colleges at present existing in the United States were to adopt simultaneously the full curriculum recommended by the college conventions of 1867 and 1869, the general incorporation laws existing in most of the states would enable any half-dozen doctors to unite in effecting the organization of a medical college, with authority to confer degrees on as easy terms as they might choose What is most needed, therefore, at this time, is not mere general resolves that the standard of medical education should be elevated, but a harmonizing and concentration of the influence of the profession in favor of the establishment of reliable and independent tribunals for determining the qualifications of all who may ask for permission to practice the healing art in any of its departments

PAPERS FOR THE SECTIONS OF THE ASSOCIATION —In another place will be found the notice of Dr R S Sutton, of Pittsburgh, Pa , chairman of the Section of Obstetrics and Diseases of Women, requesting all those who intend to present a paper in that section at the coming meeting in New Orleans, to notify him without further delay

And we take this occasion again to remind all who may be intending to present papers in any of the sections, that the by-laws of the association make it their duty to notify either the chairman of the Section or the chairman of the Committee of Arrangements of the titles and contents of their papers at least thirty days before the time of the next meeting, which this year will be on the 28th day of April, 1885

COMMA-BACILLI AND CHOLERA —From the second report of the Special Cholera Commission in India, it is stated that Dr E Klein has found the true cholera bacilli of Dr Koch in tanks of water in India, which water was being freely used by large numbers of people, among whom no case of cholera had occurred If this statement is correct, it has a very important bearing upon the question whether these bacilli have any real etiological relations to cholera or not

NEW BUILDING FOR THE ARMY MEDICAL LIBRARY AND MUSEUM —The bill appropriating $200,000 for the erection of a fireproof building for the accommodation of this very valuable library and museum has passed the House of Representatives and will doubtless become a law before the close of the present Congress

SANITARY COUNCIL OF THE MISSISSIPPI VALLEY — The Seventh Annual Meeting of this organization will be held in New Orleans, commencing Tuesday March 10 at 11 A M The subject of Cholera and its prevention will engross a large part of the attention of the Council

CORRECTION —The name "F B Brown, of Baltimore," which appears in the list of permanent members of the Association as published in number 26 of the Journal, volume III, should have been T Barton Brune, of Baltimore, Md

GAILLARD'S MEDICAL JOURNAL —We are informed that the publication of this Journal will be continued by M E and E W Gaillard, with Dr P Brynberg Porter as editor and a number of able Collaborators

RESIGNATION —We notice with regret that Dr J E Reeves, of West Virginia, has been constrained to resign his office as Secretary of the State Board of Health of that state on account of ill health

SOCIETY PROCEEDINGS

CHICAGO MEDICAL SOCIETY.

At the meeting of February 16, 1885, Dr C E Webster read a report of a case of "Malignant Growth of the Thyroid Gland "

The patient was a woman about sixty years of age Her general health was quite good The enlargement in her neck was first noticed about one year before the first consultation It commenced in one lobe of the thyroid, and rapidly extended to the adjacent glands and tissues of the neck Rubbing with liniments appeared to relieve this swelling, but it never entirely disappeared, and at the time of first seeing the patient the gland had begun to enlarge again Swallowing was difficult and the voice was husky, although respiration was not impeded The thyroid gland, larynx, trachea, and neighboring cervical glands, formed an irregular, doughy mass In the diagnosis of this case, there were two possibilities to be considered—tertiary syphilis and cancer of the thyroid The history of progression of the disease from an enlargement of the thyroid, and the fact that such enlargements of this gland in people past middle life are almost invariably malignant, rendered the diagnosis easy A short course of specific treatment, and an observation of the steady progress of the disease, confirmed the early diagnosis The patient passed on to a gradual exacerbation of her difficulty, and recently died of exhaustion

The microscopic appearance of this growth is sometimes peculiar, hardly differing from that of a benign tumor of the same organ So that oftentimes in these cases a positive diagnosis is difficult from a microscopic examination alone The reader then recited an instance in the service of the Massachusetts General Hospital, where such a doubtful tumor proved itself to be malignant by its recurrence after excision. In this case the alveoli were lined with cuboid cells and filled with a homogeneous substance

Dr F Carey inquired, by referring to the case that occurred at the Massachusetts General Hospital, if the alveoli were filled with a homogeneous substance, where, then, were the cells situated?

Dr E J Doering asked, If removal of the gland by surgical procedure would have been justifiable in the author's case

Dr L H Montgomery inquired as to the dimensions of the growth of the tumor situated on the thyroid Also, did it appear to extend uniformly in various directions, and if the author had any idea as to the functions of the thyroid? Might not the thyroid be located for the purpose of protecting the trachea, or act as a sort of reservoir analogous to that of the spleen?

Dr Webster replied in substance as follows That the lumen of the alveoli were filled with a homogeneous substance and the cells were arranged peripherically, in the hospital case that he made mention of.

Regarding the case he presented in his report At the time of first consultation the disease had progressed to such a stage that it would have been impossible to perform an operation successfully, as the deep tissues of the neck, including the œsophagus, were involved in the growth The time for an operation, therefore, would have been at the time when the growth was first noticed The size of the growth on the thyroid was as large as a hen's egg or half a hen's egg, and it extended in various directions, so that the tissues of the neck felt like a doughy mass, although the submaxillary glands were not involved in it Regarding the functions of the thyroid gland he had no theory to offer It is a ductless gland, the same as some others throughout the human system

Tænia Solium in a Child Two Years of Age —Dr C G Davis read a report of a case of *tænia solium* occurring in a child two years old and exhibited about four inches of the worm, including the head.

He was first called to see the child December 10, last, when it had not entirely recovered from an attack of entero-colitis, which it suffered from throughout the summer and autumnal months The child still had, occasionally, the usual symptoms of cholera infantum, such as vomiting, indigestion, diarrhœal, discharges, etc Immediately the child was given a number of simple remedies, with raw beef This treatment seemed to act properly In a little while portions of tænia began to appear in the discharges

The child was then given a half-teaspoonful of the French prepared preparation Peletierin and followed in an hour with twenty drops of tr jalap and a tablespoonful of castor oil This was followed by the expulsion of three or four yards of the worm, but the head was *not found* The child was then carefully nursed and its general health looked after, when segments of the worm again appeared in the evacuations.

A double dose of the quantity of peletierin, tr jalap and castor oil, as above stated, was administered, when several (7 or 8 feet) more feet of the worm was dislodged, including the head, which he then exhibited to the society

Dr Doering stated that he had treated three children having tænia, one of which was 9 years old, another 4 years of age, and a baby that was but 6 months old The last case had been fed on raw beef whilst being sick with entero-colitis He was surprised to hear of Dr Davis' success with the remedies he had used, given in such small quantities, as he had himself practiced the same method of treatment and with larger doses of the peletierin, with but partial success only

Hygroma Linguæ —Under somewhat of a disadvantage Dr Josef Zeisler reported a congenital case of this rare disease, or bearing this title, which is under his care Said he It is a strange disease of the tongue that has occurred to Emma L , who is now about 9 years old She has suffered from the trouble since her birth The child is well nourished, but her complexion is pale Her face is asymmetrical to a considerable degree, and its formation is very incommensurable in a number of respects The right half of her face is much more developed in its muscular and osseous formation than its opposite side No swollen submaxillary or cervical glands are present Her tongue was described as having the following appearance It is much thickened, the surface appears to consist of small vesicles or cysts, varying in size from a pinhead to that of a pea, lying by the side of each other in the form of mosaic pieces of work, or in a tessellated shape These cysts seem to contain a colloid mass, and this condition affects the entire visible portion of the tongue, so that no intact mucous membrane can be seen Over the middle of the tongue there extends a kind of cockscomb or carunculated excrescence, or cristate in form, of the same appearance, but presenting a more papillary or warty resemblance These crists are also found on the mucous membrane of the right cheek near the angle of the mouth In handling or touching the tongue, the surface imparts a sensation as if it consisted of oil-globules or boiled sago The movements of the organ, as well as speech, are not impeded, nor is the sense of taste in the least impaired There are no spontaneous pains proceeding from it, and pain arises only when strong compression is made upon her tongue, or, as the child says, when acid substances are taken Relatives of the child report that its tongue was formerly much larger, although it sometimes now appears to become œdematous and then grow smaller again Her parents and her five brothers and sisters have always enjoyed good health and are in a healthy condition at the present time

The writer regards this disease from a pathological standpoint as a colloid degeneration of the mucous membrane of the tongue, but he could not classify it clinically, having never seen a similar case previously A microscopical examination was not permitted to be made of any of the cysts or their contents Galvanopuncture was suggested as a remedy, which was also declined Dr E Andrews, Dr C T Parkes, Dr J N Hyde, and several other well-known physicians had seen this case, but could add nothing further of interest relative to it, nor to the treatment They had neither of them seen a similar case Dr Doering had seen this patient two years ago The tongue then presented a "sago pudding" appearance, and he presumed it still retained the same features He further stated that only two cases thus far have been reported in literature It is probable that the child will be presented before the Society at a future meeting

Exhibition of the "Koch comma bacillus of Asiatic cholera," by Dr L L McArthur —The speaker addressed the Society orally, during which he stated that Koch had devoted more time and study to the solution of the cholera problem than any other physician, and from the fact that he has so far established his cholera theory over all opposing ones, and successfully met all arguments, no little interest in the subject is felt by the people of this country, inas much as cholera may cross the ocean during the coming summer The comma bacillus of Asiatic cholera is distinguished only when magnified about a thousand times (to 1,600 times) They can be taken into the stomach with water, and although very few may be swallowed, their power of reproduction is so wonderful that in a day the victim will be suffering the agonies of a fully developed case The disease, the speaker continued, is said to be the irritation in the stomach and alimentary tract caused by the presence of these *pests* The water in the blood is lost, and if the disease is not checked or arrested death ensues The germs pass from the victim and, by going through the sewers and down the rivers, cause the disease and death to the people living along the streams The germs may also be carried in the air, or in the clothing Moisture is an essential condition for their reproduction or life If they are placed in a warm, dry place, they will die in a few weeks' time Koch, in his experiments, carried this comma bacillus through forty cultivations or generations, and the last cultivation, introduced into the stomach of a dog, brought on cholera Asiatica, and death resulted in three days

The bacilli exhibited were received from Koch's laboratory but a few days ago, and were sent by Dr Odo Betz, from Tubingen, Germany, to Dr Doering, of this city, and are the first ever exhibited in Chicago

A number of the members participated in an informal discussion of cholera Asiatica and cholera nostra, and the specimens were closely examined

The Society then adjourned

LISTON H MONTGOMERY

STATE MEDICINE

WHEELING, W VA , Feb 5, 1885

TO HIS EXCELLENCY GOVERNOR JACKSON

Dear Sir The fear which I expressed to you many weeks ago, that I should not be able, because of my poor health, to continue in the service of the state to the end of my official term (1888), I find, to my inexpressible sorrow, fully realized much sooner than I had expected   I am, therefore, compelled to lay down the office with its honors which you conferred upon me in June, 1881, and beg that you will accept my resignation to take effect Monday, the 23d inst , at 12 o'clock M

Let me tell you truly that I can find no words to fitly express my regret that I am compelled to retire from the State Board of Health, for God knows how earnestly my whole heart has been engaged in the work

From the date of the organization of the Board to the present, my association with my colleagues has been a source of continued pleasure , and from Your Excellency I have received many kindnesses which greatly encouraged my labors, and for which I shall never forget to feel grateful   Indeed, I am under many and lasting obligations to the officers of each department of the state government for courteous acts

Finally, need I assure you of my continued interest in the cause of the public health ?—in the higher and higher standard of the medical profession within our borders ?—and in West Virginia's prominence in the cultivation of sanitary science ? All these are too near my heart to be neglected or forgotten

Believe me, Very truly yours,
JAMES E REEVES

STATE OF WEST VIRGINIA,
EXECUTIVE DEPARTMENT,
WHEELING, Feb 18, 1885

JAMES E REEVES, M D , SECRETARY STATE BOARD OF HEALTH, WHEELING, W VA

Dear Sir   I am in receipt of your communication, of date the 5th instant, requesting the acceptance of your resignation as a member of the State Board of Health, to take effect on Monday, the 23d instant, at 12 o'clock, M

I greatly regret that the condition of your health compels you take this step   You have been identified with the Board from its organization until the present time   Its objects have been not only, by investigation and proper action based thereon, to promote the public health, but also to elevate the standard of the medical profession in the state   To these objects I am aware you have devoted a large share of your valuable time, aided by a ripe experience in medical and sanitary science   Your labors, in conjunction with the other members of the Board, have raised the standard of the profession to a higher plane than before attained by it, and through the operation of our health laws placed the state on advanced ground in the development of sanitary science

I had hoped that your valuable services would have been continued, at least until the end of your term, and until this department of the state's service had become so firmly established as not to be endangered by the loss of so efficient an officer

In accepting your resignation, it is with the hope that your health may be speedily restored, and that you may from time to time, by your counsel, aid the Board in carrying forward the great work for which it was created, so that the objects which you have had so much at heart may be fully realized and result in lasting good to the people of West Virginia

With the highest regard, and my best wishes for your future health and happiness, I am

Very truly yours,
J B JACKSON

FOREIGN CORRESPONDENCE.

LONDON LETTER.

LONDON, Feb 1885

At a meeting, convened by the Vegetarian Society and held in Exeter Hall, the chairman said they had served 161,000 meals during the late International Health Exhibition, or an average of about 910 per day , after paying rent and all expenses they were in a position to return the guarantee fund subscribed by their friends in aid of the experiment, and there remained a balance of over £100, besides their crockery, tables and cooking utensils   The money balance, in accordance with the public undertaking of the Society, was being spent in vegetarian meals for the poor in several large towns   Miss Anna Kingsford, M D , protested against the representations of those who seemed to think that vegetarians wished to send men out like Nebuchadnezzar to graze, to make them eat cabbages in the morning and grass in the evening   She maintained, however, that men were classed anatomically and physiologically with the apes, whose teeth were not flesh-tearing teeth   The apes used their teeth for cracking nuts, and never for masticating mutton chops or eating saddle of mutton   Flesh-eaters were liable to many diseases from which vegetarians were free   She had cured herself of tubercular consumption by living on vegetable food   Having been told that she had not six months to live, and that she must eat raw meat and drink port wine, she had gone into the country and tried cold porridge and fruit, and was there that day on that platform   She had found the shoemaker to make her shoes without leather, and she assured her audience that they did equally well for the muddy streets of London and for climbing the hills of Switzerland

During the past month the annual treats have taken place at most of the metropolitan hospitals   A pathetically interesting scene was witnessed at King's College Hospital   The resident medical officers, with the aid of sisters, nurses, students and others, had designed an evening's entertainment for the patients   All the wards were pleasingly decorated and illuminated with Japanese lanterns   A Christmas tree was set up in the great hall, which itself was brilliantly illuminated and decorated   A stage was here erected for the purpose of an entertainment devised by the medical officers, and from the various staircase landings those patients who could bear removal from the wards watched with keen interest the performance below   Many of the sick people could only watch the entertainment in a recumbent position, and were carried on their mattresses to their places In the Wigram ward, which is tenanted by patients under surgical treatment, the spray producer was converted by a clever sister into the trunk of a diminutive Christmas tree and decorated with articles humorously suggestive of the names of medical officers Thus, three cards with the motto "Play fair" suggested the name of the eminent physician In the Twining ward, distinguished by decorations of twining ivy, a sorry wag of a student ornamented the gigantic dispensing mortar with the motto "De *mortuis* nil nisi bonum," and audaciously attached to the pestle a label inscribed "Pestle-lentia deorum est donum " The entertainment in the great hall included some amateur negro minstrelsy, and particular mention may be made of a topical song in the course of which there occurred a pathetic reference to the small public attention bestowed on King's College Hospital as compared with other public institutions of a like nature It is a free hospital, and last year over 2,000 patients were taken indoors, while nearly 28,000 persons were treated as out-patients

Dr Richie, Medical Officer for Leek, drew attention, the other evening, to what he designated a very startling fact Since the insurance of the lives of children had become common in that town, he said, the rate of mortality among infants under one year had increased from fifteen to a hundred and eighty six per thousand The deaths which formerly were, for children of the age referred to, fifteen in the thousand, had during the past seven years averaged a hundred and seventy Apart from the logic of facts familiar to all who move much among the most ignorant and brutalized section of our population, it would of course be incredible that the circumstance of a small sum of money depending on the life of a child could at all affect its safety in the hands of parents That such often is the case, however, there cannot be a doubt, and statistics of any center of population in which infant insurance largely prevails—and it is very much a matter of local custom—would probably put the practice in a light which cannot but suggest the question whether parents should be permitted to realize what must often appear to be a considerable accession of wealth by the death of their children

There has been a sharp discussion in the *Times* during the last month or so on the subject of brain surgery, and there has been a good deal of acrimonious dispute as to which "school" is entitled to the distinction of having commenced such operations, although any credit attaching to the experiments is considerably diminished by the somewhat important detail that the patients whose cases have been reported appear to have all died The real fact is that neither Dr Ferrier, nor any other practitioner of the present day, ought to clamor for applause, as operations of this kind were conducted by Sir Astley Cooper more than fifty years ago If anyone turns to his "Lectures on Surgery," accounts will be discovered of operations on the skull and brain which are quite as remarkable as any recently reported, and even more so, for chloroform was not then in existence, and some, at least, of Sir Astley Cooper's patients appear to have recovered He experimented on the brain of a dog before meddling with human beings, it is not, therefore, clear why the practitioners of to day should have deemed it necessary to torture dogs A paragraph in the report prepared by the India office upon the sanitary measures adopted in India during the year 1882–83 will cause some surprise to those who have hitherto imagined that life in our eastern possessions is very often synonymous with death ‘ The sanitary progress in British regiments has overtaken that of native corps in their own country " This means that the difference between the rates of sickness and mortality between European and native soldiers is *nil*, and that the matter is altogether dependent upon the adoption of those sanitary laws which modern science has pointed out to be necessary

Dr Buckhill's article on proprietary Madhouses is by no means pleasant reading In England and Wales there are 96 private asylums, more than half of which are owned by women and people other than doctors, who of course carry on a trade in lunatics as they would in any other marketable commodity Among the reprehensible practices which Dr Buckhill cites, the most objectionable is perhaps the custom of payment by the owners of asylums to doctors and others who send them patients The customary fee is 20 per cent , and though the practice has been forbidden by the Lunacy Commissioners, Dr Buckhill asserts it to be still widely prevalent Another abuse is the letting out of keepers, on the terms that the keeper pays half, or at any rate a large proportion, of his wages to the owner of the asylum The result of this is, that in many asylums there are more keepers than patients If quiet and harmless lunatics were to be discharged from confinement,—and it has been frequently decided that such people ought not to be shut up,—the doctor considers that many asylums would be at once all but emptied The abuses of the private madhouse system are, in fact, so numerous that the efficient way of dealing with them would be to order their entire abolition

G O M

BERLIN LETTER

BERLIN, Jan 10, 1885

PROF DR SCHROEDER'S KLINIK STAFF

1 Dr Hofmeier Privatdocent, chief assistant, in charge of poliklinik and of private patients

2 Dr Winter Obstetrical poliklinik (outdoor), which numbers about 1,500 cases per year

3 Dr Bokelmann Gynecological ward, about 40 beds

4 Dr Stratz House obstetrical ward, about 60 beds

5 Dr Cohn Septic carcinomatous and puerperal fever wards, also in charge of microscopic examinations

6 Dr Ruge Assistant to Dr Cohn in microscopical work There are three volunteer doctors who live in the hospital, and whose term of service is as follows 2 months in obstetrical ward, 2 months in gynecological ward, and 2 months in Dr Cohn's ward Eight practitioners or older students attend

the labors of poor people in the city, and if operative interference is necessary they report to Dr Winter Both Dr Hofmeier and Dr Winter have student courses

NORMAL AND PATHOLOGICAL ANATOMY—FERIENCURSE

March 16 to end of April, 1885

1 Dr Jurgens (*a*) Fee, 60 marks Lasts six weeks Held at Pathological Institute Charité Pathological anatomy, with section-cutting, Monday, Wednesday and Saturday, 8–10 (*b*) Fee, 100 marks Normal and pathological anatomy and histology of brain and spinal cord

2 Dr Grawitz Fee, 40 marks Lasts five weeks In Pathological Institute Charite Practical course on pathological histology, Tuesday, Thursday and Friday, 8–10

3 Dr Weinicke (*a*) Fee, 40 marks Eight weeks 5 Dorotheen str Anatomy of brain and spinal cord, with demonstrations, Tuesday, Thursday and Saturday, 5–6

4 Dr P Guttmann Fee, 30 marks Lasts four weeks Hospital Moabit Pathological anatomy, with demonstrations

5 Dr Brœsike (*a*) Fee, 40 marks Lasts six weeks Anatomical Institute Normal anatomy, with demonstrations, every day, two hours (*b*) Normal anatomy of viscera

6 Dr Rabl Ruckhardt Fee, 30 marks Lasts six weeks Normal histology, Monday, Tuesday, Wednesday and Saturday, 8–10

7 Dr Israel Fee, 30 marks Pathological Institute Charité Normal histology

8 Dr M Wolff Fee, 30 marks 5 Dorotheen str Lasts eight weeks Examinations for bacteria, Monday and Thursday, 2–4

9 Dr Mendel Fee, 40 marks 27 Carl str Anatomy and pathology of the brain and spinal cord, Wednesday and Saturday, 6–7½

PRACTICE OF MEDICINE—FEREIN CURSUS

1 Dr A Fränkel Fee, 30 marks Charité room 7 Lasts five weeks Clinical medicine, ascultation and percussion, Monday, Thursday and Friday, 11–12½

2 Dr Litten Fee, 30 marks Augusta Hospital or 27 Carl str Lasts six weeks Clinical medicine, auscultation and percussion, 11–1 and 12–2

3 Dr P Guttmann Fee, 30 marks Lasts four weeks Hospital Moabit Clinical medicine, diagnosis, visits in wards of hospital, Monday, Tuesday, Thursday and Friday, 9½–11

4 Dr Riess Fee, 30 marks Lasts eight weeks Hospital Friedrichshain Diagnosis, Wednesday and Saturday, 11–12½

5 Dr Zuelzer Fee, 40 marks 6 Leipziger platz Examinations of urine, pathology of the kidney and bladder, Sunday, Monday, Tuesday, Thursday, Friday and Saturday, 10–11

6 Dr Lazarus Fee, 20 marks Jewish Hospital, 15 August str Therapeutics of pulmonary disease, Tuesday, Thursday and Friday, 2–3, with special reference to pneumatics

7 Dr Lewinski Fee, 30 marks 5 Dorotheen str Lasts nine weeks Auscultation and percussion, method of examinations, Monday, Wednesday and Saturday, 11–12

8 Dr Lublinski Fee, 30 marks 5 Dorotheen str Lasts six weeks Pathology and therapeutics of the nose, larynx and pharynx, with practical examinations, Tuesday and Friday, 10–11, Saturday, 11–12

9 Dr A Baginsky Fee, 30 marks 3 Johannis str Lasts five weeks Children's diseases, Monday, Wednesday and Friday, 1–2 Poliklinik

10 San Rath Dr Ehrenhaus Fee, 20 marks 40 Lothringer str Lasts five weeks Pathology and treatment of diseases of children Poliklinik

11 Dr E Grunmach Fee, 30 marks 5 Dorotheen str Lasts six weeks Auscultation and percussion, Monday, Wednesday and Saturday, 2–3 (*b*) Diseases of respiration and circulation (fee, 20 marks), Tuesday and Friday, 2–3

12 Dr Ewald Fee, 30 marks, 31a Potsdamer str Diseases of the digestive organs, Tuesday, Thursday and Friday, 10–11

13 Dr B Baginsky Fee, 30 marks 24 Markgrafen str Laryngoscopy and rhinoscopy, three times a week, 6–7

NERVOUS DISEASES AND ELECTRO-THERAPY

1 Dr M Bernhardt Fee, 30 marks 58 Markgrafen str Lasts five weeks Electro diagnosis and therapy, Tuesday, Friday and Saturday, 6–7

2 Dr Remak Fee, 30 marks 40 Mauer str Lasts five weeks Electro diagnosis and electro-therapy, with clinical demonstrations, Tuesday, Thursday and Saturday, 6–7

3 Dr Weinicke Fee, 30 marks 5 Dorotheen str Diseases of the nervous system, Monday, Wednesday and Friday

4 Dr Eulenburg Fee, 30 marks 27 Carl str Lasts five weeks Electro-therapy and neuropathological diagnosis, Monday, Wednesday and Saturday, 3½–4½

5 Dr Oppenheim Fee, 30 marks Charite Last six weeks Diseases of the nervous system and electro-diagnosis, Tuesday, Thursday and Sunday, 9–10

SURGERY

1 Dr Hahn Fee, 40 marks Hospital Friedrichshain Lasts twelve weeks Clinical surgery, Wednesday and Saturday, 8–11 Operations, Sunday, 8–10

2 Dr Hans Schmidt (*a*) Fee, 30 marks Augusta Hospital Lasts five weeks Surgical treatment and after treatment, Wednesday and Saturday, 3½–5 (*b*) Fee, 30 marks Surgical examinations, Monday and Thursday, 6–7

3 Dr Busch Fee, 30 marks 40 Dorotheen str Diseases of the teeth One month

EYE DISEASES

1 Dr J Hirschberg Fee, 40 marks 36 Karl str Lasts ten weeks Practical course, with clinical demonstrations, three times a week, 12–1

2 Dr Horstmann Fee, 30 marks 6 Potsdamer str Ophthalmoscopy and refraction, etc, Monday, Wednesday and Friday, 5–6

DISEASES OF THE EAR

2 Dr Schwabach Fee, 30 marks Koniggraratzer str 42 Clinical course, with examinations in catheterismus of the Eustachian tube, Monday, Wed , Friday, 6–7

2 Dr L Jacobson Fee, 40 marks 5–9 Ziegel str Lasts six weeks Practical course, with demonstrations

3 Dr B Baginsky Fee, 30 marks 34 Markgrafen str Diseases of the nose

GYNÆCOLOGY

1 Dr A Martin (*a*) Fee, 60 marks 85 Elsasser str Examinations and operative demonstrations, 12–3, operations from 7–9 and 11–12 (*b*) Fee, 75 marks Gynecological operations, 7–9 evenings (Schulze-Winckel phantom)

2 Dr Landau Fee, 40 marks 40 Lothringer str Demonstrations and examinations, Tuesday and Saturday, 11–1

3 Dr H Lohlein Fee, 40 marks 40 Tauben str Diagnosis

4 Dr Hofmeier Fee, 40 marks 14–16 Artillerie str Diagnosis, daily, 12–1

5 Dr Veit Fee, 40 marks 16 Steinmetz str Diagnosis, Monday, Wednesday and Friday, 10–11

6 Dr Wyder (*a*) Fee, 40 marks Charité, Obstetrical operations, with demonstrations from poliklinik, daily, 8–9 (*b*) Fee, 50 marks Gynecological operations, daily, 3–4½

DERMATOLOGY AND SYPHILIS

1 Dr G Lewin Fee, 30 marks Charité, Syphilis, etc , Wednesday and Saturday, 10–11

2 Dr Lassar Fee, 30 marks 19 Karl str Skin

3 Dr Zuelzer Fee, 20 marks 6 Leipziger platz Skin

4 Dr Behrend Fee, 30 marks 27 Elsasser str Skin

5 Dr Kobner Fee, 30 marks 111 Friedrich str Skin and syphilis

I have compiled this table with some care, for the benefit of those who contemplate a trip to Europe during the spring As it gives fees, localities and hours, it will prove a useful guide I have read with some interest the address of Mr Lawson Tait upon his return to Birmingham I have been also somewhat amused at the desperate glee with which he snatches at the straw thrown out by the "eminent surgeon of thirty years' standing and enormous clinical experience" in relation to listerism Some pretty good surgical work is being done all the time in Germany The amount of material is very large and very varied The number of abdominal sections made is also large The results here are good, although much of the work is done in a *general* operating room, and before a whole class of students Many have come from pathological and anatomical work, some possibly from infected wards Now it is a self evident fact that such results could not possibly obtain under any other conditions than those of full listerism, bichloride of mercury and iodoform If it is quackery, it is the mightiest discovery for the weal of suffering humanity that has characterized surgery for many a year—and if it is quackery, they who practice it must be quacks—and the following is a right royal and mighty one Fortunately for surgery, the opinion of the minority does not weigh in the balance, and fortunately for German surgery, much of which is done under the most unfavorable conditions, strict antisepsis is still the rule The Germans have given us the best pathology in the world, and as a thinking people their practice is based largely upon this Tait's treatment of uterine tumors has not a very firm hold upon German practice The operation is quite as difficult and quite as dangerous as a myomotomy, and the results are not as good nor as permanent Dr Veit is using sheep-gut ligatures soaked in carbolized solution and hardened in alcohol I have seen him do some plastic work lately—an Emmet and a ruptured perineum—in which he used the gut and the continuous stitch The operations were done quickly and with great neatness Dr Veit is already in the very foremost ranks of German gynecologists, although still a young man, and his private practice is about as large as that of any specialist here, except, perhaps, Dr Schroeder But what is called an Emmet's operation here is not a true Emmet, it is more a partial amputation They remove first quite a large piece of the anterior lip, and then of the posterior The edges of the anterior incision are brought together by sutures, before the posterior part is snipped off I have not yet seen a "paring" of the edges of a laceration, and the bringing of the flaps together with a suture through the anterior and posterior lip at the same, as we are accustomed to do it a home Dr Veit's perineo plastic work is very pretty and quickly done

H R B

DOMESTIC CORRESPONDENCE

PHILADELPHIA LETTER

PHILADELPHIA, Feb 17, 1885

MR EDITOR

We may expect shortly again to be in the agonies of a canvass for a professorship, Prof Mallet, but recently elected to the chair of chemistry in Jefferson, having resigned At this rate, the trustees of that institution will greatly enjoy their position, and perhaps they may come to the conclusion that for a time at least "honors are not easy" Thus far, the only candidates who have appeared being Philadelphians, the canvass may be regarded as not yet begun, inasmuch as no citizens of this metropolis need apply We would respectfully request the chemists from afar off to put in their applications

The winter medically has been quiet Very little practice, nothing of special interest in our societies But hold! we forget, our county society has been holding a series of meetings for the discussion of an Act to create a Board of Examiners and Licensers of medical men The debate was earnest, even acrimonious at times, and to an outsider there were many curious features One school was well represented and fought bravely on one side, another school was equally earnest in opposition, while yet other schools appeared so little interested that their faculties were only conspicuous by their absence Slowly the meetings dwindled down, until at the last a handful of members went through the form of voting, and as far as can be judged, the matter now seems to have quieted down As the whole subject is to come up in the form of a report to our State Medical Society next May, we may look for a renewal of the effort about that time

We have just been treated to our share of horrors, in the burning of a portion of our Almshouse, the Insane Department About twenty of the poor insane were thus put to death It looks just now as if each department of our city government were trying to hoist from its shoulders the onus of the deed Knowing well the calibre of several of the Board of Guardians, we shall be greatly surprised if they do not put the responsibility where it belongs One good will result already the fearful overcrowding, the absence of proper watchmen to guard against just such a calamity, and a host of other evils have been shown, and our city fathers will have the opportunity given them to provide better quarters It is proposed, as soon as can be done, to separate the almshouse proper with its hordes of able bodied paupers from the indigent sick or insane This will be a just arrangement, for hitherto it has frequently occurred that the worthy sick have refused to accept a bed in this hospital because it was the "Poorhouse"

From the present outlook, it appears as though, after much hard work for the last ten years, we are to have a State Board of Health The people now seem to have been educated to a knowledge of the value of such a body, and are aiding the profession in their efforts to that end A committee of our State Medical Society met the Judiciary Committee of our Legislature last week, and gave these lawmakers their views on the subject Now, if the bill passes, and the composition of the Board can be kept out of the hands of politicians, the old Keystone State will at last be able to present herself *in the line* as prepared to prevent disease, or to speedily stamp it out, should it make its appearance

We have a new candidate for medical preference, in the shape of the Medical Journal which Messrs Parke, Davis & Co have transplanted from Detroit It presents a neat appearance, and as its backers have plenty of money and are very determined in what they undertake, it is probable that the new Journal may continue with us awhile We predict, however, that certain changes may become imperative, but as we do not desire to pose as a prophet, we shall merely say, "told you so," when these occur in the near future We have now the Medical News, Messrs Lea's organ, the Medical and Surgical Reporter, the Medical Times, the organ of J B Lippincott & Co, the Medical Bulletin, which is of the firm of F A Davis & Co, the College and Clinical Record, which is devoted to the interest of the Alumni of Jefferson, and is expressly announced as *not* the organ of that school, the Polyclinic, which is edited in the interests of the institution of that name, and the Medical World There may be a few more, but as they do not burden our table, we are unable to quote them

In order to prepare the common people for our possible visitor next summer, our societies and at least one of our colleges have been kindly circulating postal cards, asking the profession to call and view, gratis, a specimen of the "comma bacillus," or "cholera bacillus" I believe that great care has been taken by Prof Koch, from whom each of these little gentlemen has been received, hence they are real, simon pure, to cage the animal so securely that he cannot get loose, and we are reasonably secure against the importation of the pest by this avenue It is an excellent idea, and soon we shall find our gamins selling small microscopes at the street corners by which each may inspect for himself and be able at once to detect its earliest arrival

We are rapidly approaching our spring delivery, and we look for the usual outpour of doctors, dentists and pharmacists We cannot speak too strongly our praise of our School of Pharmacy For many years it has stood as the educator of our apothecaries, and has been the means of doing a world of good As long as we pour out M D's so illy prepared, let us endeavor to prevent a portion of evil by furnishing pharmacists skilled to make their crude efforts at least harmless to the unfortunates who recklessly employ the "new young doctor," because he is cheap It has often been said that as the stream cannot rise above its source, so the medical profession will improve in ability, as is the demand by the people for educated physicians The people prefer cheap goods and they get them They demand humbugs, and the supply equals the demand Apropos of this, "Monsieur Tonson, come again" Diploma Buchanan is once more in the courts and diplomas are for sale Nothing is so easy to check as this When the German government took hold of the matter, and after investigating it through our valuable Consul, Mr White, and their own Barons, Theilman and Schlotzer, it was finally required that a diploma, to be useful in the Prussian Empire, must be attested by the American Medical Association, through its Permanent Secretary Why should not this plan be followed by all foreign governments? No bought diploma, nor one emanating from a bogus college, could prove of value to its possessor save in our own free land As we cannot have a general law in America, the only hope is the plan pursued by Illinois, and then the gradual dying out of the brood of bogus doctors may some day give the name of medical doctor its proper high position Yours, PHILADELPHIA

419 Penn Avenue,
Pittsburgh, Pa, Feb 23, 1885

Dr N S Davis, Editor

Dear Sir Please insert the following card as soon as convenient Gentlemen desiring to read papers before the Obstetrical Section at the next meeting of the Association at New Orleans will please send in the subjects of their papers, as there is room left for only a few more

Very respectfully yours,

R S Sutton,
Chairman of Obstet Section

NECROLOGY

New York Polyclinic, Feb 21, 1885

N S Davis, M D , Editor Journal of the American Medical Association

Dear Doctor At a meeting of the members of the medical profession attending the New York Polyclinic, the following resolutions were this day unanimously adopted

Whereas, In the inscrutable providence of God, Professor Louis Elsberg has been removed from this life,

Resolved, That in his death science has lost an earnest and indefatigable student, the medical profession an honorable member and widely known teacher, and society one with broad and humanitarian sympathies

Resolved, That we offer to his family assurances of sympathy, and, as a testimony of our regard for his character and attainments and a sense of our personal loss in his death, that we, the members of the class of the New York Polyclinic, attend the funeral in a body

Resolved, That copies of these resolutions be sent to his family, to the Faculty of the Polyclinic, and to the medical press *of the country*

Eugene L Tridenberg, M D ,
J T Herrick, M D ,
W T Gott, M D ,
Jno C Berry, M D
M T Moore, M D , Chairman
Committee on Resolutions

Fraternally,
Moses T Runnels, M D , *Secretary*

MISCELLANEOUS

Nashville, Tenn , Feb 21, 1885

The fifty-second annual meeting of the Medical Society of the State of Tennessee will be held at Nashville, commencing the second Tuesday in April, and will be in session three days, April 14, 15 and 16 The Society will be called to order on the 14th, at 12 M , in the State Capitol

The members are reminded that at the last meeting of the Society the initiation fee was fixed at $5, the assessment on members in attendance, $2 , for those not present, entitling them to the transactions, $1

The volunteer plan in regard to papers succeeded so well last year, that it is hoped the members will show the same interest in the welfare and progress of the profession in Tennessee, and come prepared with papers and reports of cases of interest Those contemplating presenting papers are requested to notify the secretary at an early day

The American Medical Association meets in New Orleans April 28, and members of the profession who desire to attend that should attend this meeting, so as to be appointed delegates The last meeting of the Society was the most successful ever held in the fifty-two years of its existence, and this one promises to be equally so The railroads have granted special rates, and some valuable essays and committee reports have been promised

C C Fite, *Secretary*

The Louisville & Nashville railroad will sell round trip tickets at 4 cents a mile on the 13th and 14th, good to return until the 18th The tickets can be bought at all stations in Tennessee

The Nashville, Chattanooga & St Louis railroad will sell round trip tickets at 4 cents a mile on the 12th, 13th and 14th, good to return until the 18th The tickets will be sold from the following stations only

Chattanooga, Wauhatchie, Whitesides, Shellmound, Bridgeport, Stevenson, Sherwood, Cowan, Decherd, Winchester, Huntland, Fayetteville, Estell Springs, Tullahoma, Manchester, Morrison, Smartts, McMinnville, Rock Island, Sparta, Wartrace, Shelbyville, Belle Buckle, Fosterville, Murfreesboro, Lebanon, Silver Springs, Kingston Springs, Dickson, McEwen, Waverly, Johnsonville, Camden, Huntington, McKenzie, Dresden, Martin, Paducah Junction, Union City

The East Tennessee, Virginia & Georgia railroad will sell round trip tickets at 4 cents a mile on the 12th, 13th and 14th, good to return until the 18th

N B —The railroads will not recognize certificates for return passage, so these round trip tickets should be secured in all cases, *and bought during the business hours of the day*

The granting of these special rates is a courtesy shown by the railroad managements to the Society, and their rules should be cheerfully complied with

SANITARY COUNCIL.

The Executive Committee of the Sanitary Council of the Mississippi Valley has fixed the date of the seventh annual meeting of the Council for Tuesday, March 10, prox , and in the city of New Orleans This is about a month earlier than its meetings are usually held, and the Committee assigns as a reason for the change the probability of Asiatic cholera appearing in the country, and the uncertainty concerning National legislation on public health matters Invitations are extended to all state and local health authorities in the Valley, and to representatives of commercial and transportation interests

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, United States Army, from February 14, 1885, to February 20, 1885

Patzki, Julius H , Captain and Assistant Surgeon, leave of absence further extended seven months on surgeon's certificate of disability (S O 40, A G O , February 17, 1885)

Perley, L O , Captain and Assistant Surgeon, granted leave of absence for one month, to take effect about March 5, 1885 *(S O 16, Department of Dakota, February 10, 1885)*

Robinson, S Q , Captain and Assistant Surgeon, relieved from duty at St Spokane, W T , and ordered for duty as Post Surgeon, Fort Klamath, Oregon (S O 23, Department of Colorado, February 9, 1885)

Kean, J R , First Lieutenant and Assistant Surgeon (recently appointed), assigned to duty at Fort Sill, Indian Territory (S O 23, Department of Missouri, February 11, 1885)

ORIGINAL ARTICLES

THE RELATION OF THE LITERARY TO THE MEDICAL COLLEGES

BY E T NELSON, PH D, PROFESSOR OF PHYSIOLOGY AND GEOLOGY, OHIO WESLEYAN UNIVERSITY, DELAWARE, OHIO

A paper read before the Second Annual Meeting of the Ohio State Sanitary Association, held at Columbus, February 5 and 6, 1885

MR PRESIDENT AND GENTLEMEN OF THE ASSOCIATION

There lies upon my study-table a report, by the Illinois State Board of Health, entitled "Medical Education in the United States and in Canada"

Though not primarily intended for non-professional readers, it is a work whose pages I have turned a great many times during the past two years

With a peculiar pleasure have I glanced at the names of the one hundred and thirty existing medical colleges in these two English-speaking and otherwise closely-united countries

I have examined with great care their requirements and courses of study, have noted their list of matriculates, the states from which their patronage has been most largely drawn, and have calculated the ratio of graduates to the total number enrolled

With no less zeal have I attempted to subdivide my sympathy over the eighty-eight institutions which have been, but are not For many of these colleges I sorrow as those who have no hope They are dead, and that is the only thing that can be said about them

Others never had any life, save in the mind of some Buchanan or other as notorious victimizer of his race

Many of these institutions, however, have had a history at once honorable to all concerned They have merely lost their personal identity through consolidation, or have yielded to the inevitable ebb and flow of society

Very naturally, the institutions of our own commonwealth have claimed more than their full share of attention

In the total number of medical colleges and in the number of first-class funerals, the record of this state has been surpassed only by that of New York Twenty-four medical colleges have been born in Ohio Ten died in unconscious infancy, while fourteen remain the objects of a layman's anxious solicitude

I am profoundly thankful that no State Board of Health (or of Lunacy) has ever found it necessary to write up the literary institutions of Ohio Their record would be still more fatal to state pride and state honor In numbers we have not been willing to be second even to New York In quality we range from that nameless university which had, according to a late report by the Commissioner of Education, two professors, three students, and a library of one hundred and twenty-seven volumes—I say we range from this nameless university all the way up to those noble institutions whose professors and alumni are represented upon this programme and in the offices of this association

Until recently there has been but little connection of any kind between the literary and the medical colleges of Ohio In some instances there has been a seeming antagonism, in others, a spirit of mutual *indifference* In no case have the academic and the professional been regarded as concurrent factors in a single educational system To be sure, several of our leading universities have their medical departments, but, as I rejoice to learn, the latter are almost as free and untrammeled as where no such organic union exists

Moreover, such a union, desirable as it is in very many respects, is found to be one of convenience rather than of necessity It undoubtedly ensures a somewhat better utilization of the teaching force, and thus is to be commended on the score of economy

By associating the two in the minds of the students from the very commencement of their preparatory studies, there may be a somewhat increased attendance, especially at the Medical College, but it still remains that the two schools must preserve their individuality and carry on their work separately

It is, however, not a question of *organic* union that has led me to select this topic If I felt qualified to discuss so important a matter I certainly am not authorized to make any overtures on the part of the literary institutions Nor is this association prepared to receive them on behalf of the medical colleges, if tendered

The relation between the literary and the medical colleges, if you please, between the academic and the medical men of our commonwealth which I advocate, is rather one of comity, co-operation and goodwill—a pooling of mutual interests in order

1st That the standard of education, general as well as professional, may be elevated

2d That a much larger number of college graduates may be drawn into this vocation of medicine

3d That scientific and rational instruction in physiology and hygiene may be given to the pupils in the universities, academies and high schools of our state

4th That, as a result of these reforms, the principles of hygienic and sanitary science may be made known to the entire citizenship of our beautiful commonwealth

The time, given to me by the kindness of your committee, will not permit of more than a brief unfolding of this subject, in the four subdivisions just indicated

I Such a union would elevate the standard of education

Some months ago, I received a letter from a warm personal friend—himself a member of the Illinois State Board of Health—and the one to whom was committed much of the labor of compiling their report, though his name does not so appear From him I obtained, as it were, an inside view of these matters and gleaned certain facts not discoverable in the published report, at least not without much study and very careful comparisons

In the prosecution of their work they have found it necessary to adopt a schedule by which to grade the medical institutions of the country According to that standard there are, in the United States, ten first-class medical colleges A list of these accompanies the letter

As I am not here this afternoon to advertise any one special institution over another, it is certainly sufficient, for the purpose now in hand, to state that not one of these colleges is located within the borders of our own commonwealth

I am well aware that it is the prevailing fashion to decry the educational institutions of Ohio, and the universities and academies far more than the professional schools There is a deep-seated prejudice against a system that has authorized the founding of institutions which are necessarily rivals from the start, or which have so insufficient an endorsement as to preclude the possibility of their doing true educational work No one can be a student in a New England University, for a single week, without hearing of the "Fresh-water" colleges of Ohio, just as if an institution of learning must breathe the salt air daily in order to possess the true aroma of culture

In a late number of the *Independent*, while admitting many of the evils spoken of, I have attempted to show that the multiplication of colleges has carried the means of obtaining, at the least, a fair education into scores of communities and into thousands of homes where otherwise ignorance and vice would have prevailed An examination of college catalogues proves that the local attendance at any of our institutions of learning is out of all proportion to the population At one university, eighty-four out of ninety students are recorded as coming from the county in which the institution is located At a second, 155 out of 340, at a third, 162 out of 783 The largest number of students leaving any county in the state, to attend colleges located elsewhere, is probably less than *fifty* This argument is no less true for a medical college than for a literary one

Granting that we are not half so bad as we seem to others, let us, nevertheless, examine in a candid spirit the grounds of these criticisms, and thus ascertain, if possible, why the medical colleges of Ohio, in which we justly take so much pride, are not crowned with the same honors by our friends in other states

With the exception of a slight criticism as to the length of the college year, and a severe one as to the number of years in the medical course, the trouble lies wholly at the threshold Not a few of the institutions in the so called first class have so elevated the standard for admission as to make a preliminary training in some good classical and scientific school an absolute necessity

In one instance an examination is required in the following branches of study, except in the case of those students who bring evidence of still higher attainments The essentials of an English education, including composition and writing from dictation, algebra, arithmetic, including the metric system, and geometry as an elective Latin, including translation of easy Latin at sight, German or French, with special credits for both, physics, chemistry and botany, at the option of the candidate

At another college special honors are paid to the literary side of the student's preparation by waving all examination, in the case of those who have successfully passed the classical entrance into one of the great Eastern universities, Harvard, Yale, Princeton, or the University of Pennsylvania As this classical entrance examination is almost equivalent to that demanded for the "B A" degree in a number of institutions that I could name, some of which, unfortunately, are located in Ohio, you will observe that very advanced ground has been taken *

It is very evident that the trend of the times is in favor of a higher and more complete preparation for the medical calling

By how much do I anticipate this trend when I plant myself firmly upon the platform of requiring a diploma from some recognized university or scientific school as the *sine qua non* for entrance into the future medical college of Ohio and of the country? As we shall all step upon that platform in twenty years, if we live, why waste two decades in getting ready to move

Nothing less than this is in keeping with the dignity of the profession or in harmony with the severe studies in its curriculum Pardon a personal reference It has fallen to my lot to pay some attention to the sub science of physiology I have now progressed sufficiently in my studies to recognize the entire boundlessness of this field for research In the prosecution of my studies I recall and employ

---

* Several of our State Boards have insisted upon requirements *no less* severe

Many of our medical colleges are advocating a standard which is quite satisfactory as witness the following

The general demand for a good preliminary education of those about to enter our profession is shown by the recent utterances of the American Medical Association and the enactments of several State Boards of Health We desire to call especial attention to the fact that in several States the diplomas of such schools as do not require an examination preliminary to entrance, are not accepted as qualifying for practice a somewhat protracted training in mathematics taken in an Eastern university and then fail for lack of additional knowledge in this department. In mechanics and in physics I have already been compelled to go beyond the point my teachers left me twenty years ago. In all that pertains to the brain, including the mental and the moral elements of the mind, I have not had sufficient training to confidently take a single step alone. In short, I have early discovered that to be a teacher of physiology requires more preparation, at least in certain lines, than is given to the undergraduate in any American university. You will pardon me, I trust, for adding that a practitioner of medicine must understand physiology. In all this I have taken no note of those studies usually called disciplinary, if such there be in a college course, nor of their reflex influence in training the mind for severe and protracted investigations, but only of those sciences and subjects whose principles are directly employed in physiological research. Were my time unlimited this afternoon, the argument could be made much stronger by discussing the influence of academic training in general upon habits of thought and powers of discrimination, but I forbear.

I have referred at some length to the science of physiology, not because it is the *most* important study in a course of medicine, but because it happens to be the only one with which I am at all familiar. What is true for physiology, however, must be true for "therapeutics," for "theory and practice,"—indeed for all the studies in the medical curriculum.

A single example proves the rule.

The theological seminaries of our country have already been compelled by public sentiment to meet this problem of academic *versus* professional training, and have solved it (at least, so it seems to me) in a very wise and happy manner.

Having arranged a scheme of study, extending over perhaps three years, they admit to its privileges two classes of students.

1st. Young men who have not had the advantages of a full collegiate training. They are admitted freely to the several courses of study, are examined upon the same from time to time, and, on completing the required work in all the departments, receive a certificate to that effect.

Although, in a sense, licensed to practice preaching, they are *not* graduates, have no voice in alumnal meetings, nor in the election of alumnal trustees. On the other hand, young men bearing a diploma and a degree from some university or college, receive, on completing the same course of study, and after passing the same examination, the degree of Bachelor in Divinity. They constitute the body of alumni and are recognized as such throughout the church.

The good results of this advanced step are seen at a glance.

The future clergymen are taught that, no matter how it may have been in the times of their fathers, the present age is demanding a cultured ministry.

The theological seminaries have received a greatly increased attendance, while at the same time scores of young men have been sent to college who otherwise would have been satisfied with a common English education.

An important difficulty must have already suggested itself to our minds. While, legally, anybody can preach, it is not so with the practice of medicine. The only door to the profession is through the medical college—the "open sesame," a degree. The laws do not and cannot allow of distinctions in the preparation. They may specify a minimum, but are unable to rightly honor a maximum preparation. That must await the enlightened action of some medical faculty. Before many moons have come and gone some institution of medicine will plant itself upon this platform, and though at first the attendance and revenues may be somewhat diminished, it will in the end prove the most popular step ever taken in our educational history.

May God speed the day, and also grant that it fall to the lot of some Ohio college to lead the van.

We now notice that, as a result of this friendly co-operation between the academic and the professional schools, an increased and ever increasing number of college and university graduates will be drawn into the vocation of medicine.

Certainly if the medical schools should be closed to all persons except those wearing literary degrees as I have suggested, but no less certainly, if through these increased requirements all future disciples of Æsculapius have the importance of a well-rounded culture impressed upon their minds. I have taken the trouble to examine, upon this point, the records of the inststution, with which I am connected.

Out of the first five hundred graduates, thirty, or exactly six per cent, entered upon the medical profession. From the ranks of the next two hundred, nine per cent became physicians. Of the next hundred, twelve per cent, while from a recent class of thirty members no less than eight selected medicine, seven of whom have already entered upon its practice. I hear a like favorable report from other universities in the state.

It would, however, not be safe to conclude that there is a sudden stampede toward the medical profession, or that anyone is attempting to "bear" this market.

The enrollment in the several medical schools of the state, save when affected by the hard times, shows a healthy growth without any spasmodic increase in numbers. For this reason the interest in medical training found in our universities is one of the cheering signs of the times, and one which, if reciprocated by our medical friends, will soon force to speedy solution the question of entrance requirements.

The almost phenomenal success of university graduates, while pursuing medical studies, is having a very marked influence, and in the right direction. The honors and prizes obtained by these graduates of our literary institutions are out of all proportion to their numbers. When, from a single class in an Ohio university, eight young men select the vocation of medicine, and in its prosecution attend five different medical colleges, in four different states, and

2d That a much larger number of college graduates may be drawn into this vocation of medicine

3d That scientific and rational instruction in physiology and hygiene may be given to the pupils in the universities, academies and high schools of our state

4th That, as a result of these reforms, the principles of hygienic and sanitary science may be made known to the entire citizenship of our beautiful commonwealth

It would, however, not be safe to conclude that there is a sudden stampede toward the medical profession, or that anyone is attempting to "bear" this market

The enrollment in the several medical schools of the state, save when affected by the hard times, shows a healthy growth without any spasmodic increase in numbers For this reason the interest in medical training found in our universities is one of the cheering signs of the times, and one which, if reciprocated by our medical friends, will soon force to speedy solution the question of entrance requirements

The almost phenomenal success of university graduates, while pursuing medical studies, is having a very marked influence, and in the right direction The honors and prizes obtained by these graduates of our literary institutions are out of all proportion to their numbers When, from a single class in an Ohio university, eight young men select the vocation of medicine, and in its prosecution attend five different medical colleges, in four different states, and zens and prospective citizens of the Keystone State study in the colleges of New York, Maryland, Ohio, Michigan and other states As soon as it is known that no one can practice in this wealthy commonwealth unless he passes the state examination, such persons will study in the highest grade schools, and in those whose graduates show the smallest percentage of failure before the Pennsylvania Examining Board Hence, if our schools are the best equipped and supply the best education, men will not pay their money to the teachers, boarding-house keepers, and merchants of other states, but will attend our own schools, and thus increase the business prosperity of Pennsylvania The competition of low grade colleges, whether in this or neighboring states, would not then tend to paralyze the efforts of institutions of high educational standard There would be no longer a premium offered for quick graduation after two years' study and a five minutes' oral examination in each of seven branches

Another indirect advantage would be this that students could study in several institutions, and thus gain the benefit of hearing the foremost teachers of various schools, instead of being cognizant with the precepts of but one faculty The former method of study is certainly the most elevating, as it broadens professional knowledge

The division of labor resulting from examinations being held by a non-teaching board, having committees in different parts of the state, would make it possible to hold written and manipulative, as well as oral examinations, and thus do better justice to candidates than is possible by an oral examination alone Again, the examinations not being held all at one time of year, would further accommodate intending practitioners and lessen the labor of the examiners As it is now, the college faculties, with great inconvenience to themselves, and often with injustice to the pupils, hurry through the examinations of several hundred students in a few days A gentleman, now dead, who was for years a professor in a large medical school, once told me of a case where a man who failed to pass his examination was actually graduated, because of a clerical error that occurred in the hurry of commencement time Neither of us knew how many people owed their deaths to that accidental physician Bright men may have been rejected by similar errors made in hasty examinations The state board examinations would be conducted leisurely, and, being partly written, would show by the records whether a man was unjustly recorded He would also have the right to a public appeal from the report of the board, which now he has not The college examination is, as it should be under the present arrangement, the private business of a private corporation, and therefore sealed from public inspection

Another advantage which deserves consideration is the power of revoking a man's license to practice, which would be possible if a State Examination Board is instituted His diploma cannot and could not be taken away, but his certificate of knowledge, character, etc , could be canceled or withdrawn by the board if he was convicted of criminal malpractice or similar crime

The last reason for advocating the law is cogent, but to my mind deserves little attention, because it is a selfish one, which should influence us much less than those previously discussed Such an examination would weed out and keep out of the profession those persons who, though ignorant of medical science, accept professional duties and emoluments, and thus increase the difficulty of an educated physician gaining a livelihood There are, undoubtedly, too many physicians for the needs of the closely settled districts Fewer doctors, and better ones, would be a boon to most sections of the state The state examination would effect both objects The legal profession has, I believe, certain restrictions to indiscriminate admission to the bar Why should not the medical profession have some similar protection.

Dr Isaac Ashe speaks of districts in Scotland where sixpenny charges are made by physicians, and says he knows of an English town of 50,000 inhabitants where one shilling charges are made for medical advice ["Medical Politics," the Carmichael Prize Essay for 1873, p 33] He quotes from the *Medical Press and Circular*, of September 11, 1872, p 216, the following charges adopted by a practitioner of thirty years' experience "Midwifery, two shillings and sixpence, advice, sixpence, consultations, one shilling" Is there a barrister in England, or an attorney-at-law in Pennsylvania, who accepts such insignificant fees for professional services? Yet the position of the medical profession in Pennsylvania is little better than that mentioned in England. The poor estimate put upon medical service is due to the overcrowded state of the profession and the inferior quality of much medical work, both of which conditions would steadily decrease after the initiation of a state examination

That the medical profession desires the adoption of a state examining board may be assumed from the recent action of the Philadelphia County Medical Society At a meeting of the present month, in which this and kindred educational topics were fully discussed by college professors, and practitioners, both general and special, the following resolutions were offered After postponement for printing and circulation they were adopted

Resolved, That the Philadelphia County Medical Society believes that the status of the medical profession of this state will be elevated by the establishment of a non teaching Board of Medical Examiners, whose certificate shall be the only one accepted by the Prothonotary's office for physicians registering after January, 1886

Resolved, That the other county societies of this state be requested to advocate the establishment of such a board at the next meeting of the State Society, and to discuss the matter, prior to that meeting, with the members of the General Assembly resident in their counties

Resolved, That the corresponding secretary be directed to transmit a copy of these resolutions to the secretary of each county society, with the request that immediate action be taken, and reported to this society

Resolved, That a committee be appointed to draft a law creating a State Board of Examiners, for the examination of all persons for license to practice medicine, the said law to be presented at the next meeting of the Medical Society of Pennsylvania by the Philadelphia delegates to that meeting

Having spoken of the advantageous action of a state examining board, I must hastily consider the objections that will be raised to its enactment

It will be said that physicians living outside of this state, but near its border, are often called to attend patients in Pennsylvania Very well, let them be examined by the Pennsylvania Board, and register in the county of this state nearest their residences Shall a physician of New Jersey, Maryland, Delaware, New York or Ohio practice continuously in Pennsylvania, without being subjected to the same examination as residents of this state? Certainly not Those, however, who come into the state as consultants with duly licensed practitioners of this state should, of course, be excused from the state examination So should dentists who do not practice medicine, whether residents or non-residents of the state In the same manner midwives, who attend the very poor in cases of confinement, should be exempt from professional examination, though they undoubtedly should be registered and give some evidence of obstetric knowledge

A physician changing his residence within the state would merely be required to register in his new locality, but would have to pass no second examination Nor should those now legally registered and practicing be required to pass the state examination

It will be urged as an objection that there are physicians who desire to practice special systems of medicine, and that such a state examination would exclude these from practice Not at all Let the board examine all candidates on anatomy, physiology, pathology, hygiene, surgery, obstetrics, chemistry and materia medica only, omitting theories of medical practice and therapeutics entirely from the schedule

I have thus advocated, Mr President and gentlemen, a measure which will, I believe, add to the wealth and prosperity of the State of Pennsylvania, and elevate the profession of medicine, for whatever elevates the latter must increase the former The wealth of a community is the health and lives of its citizens Every useful life saved, every illness shortened, adds to the public treasury The educated physician may do both, the ignorant physician does neither I pray you to aid in cultivating the one and eradicating the other

A CASE OF GOITRE WITH OBSTRUCTION---TRACHEOTOMY---SOME OBSERVATIONS ON TRACHEAL TUBES---EXHIBITION OF PATIENT AND MODIFIED TUBES FOR LOW TRACHEOTOMY

BY D W GRAHAM, A M, M D,

PROFESSOR OF SURGERY WOMAN'S MEDICAL COLLEGE SURGEON TO THE CENTRAL DISPENSARY SURGEON TO THE PRESBYTERIAN HOSPITAL

Read before the Illinois State Medical Society, May, 1884

I desire to report this case, both because I think it sufficiently interesting and instructive to put on record as a part of the proceedings of this society, and because it affords a good occasion to present the results of some studies and observations on tracheotomy tubes, which results, I venture to hope, may be of some practical service to the profession

May Parker, 13½ years old, in last December first noticed an enlargement of the thyroid gland She came under my observation for treatment in February following, since which time she has taken pretty large doses of iodine, most of the time in the form of the compound solution The gland was soft and symmetrically, but not greatly, enlarged—not essentially different from what you now observe—although it has diminished somewhat in size since the operation The isthmus was relatively more enlarged than the lobes, extending from the larynx down to the sternum During the four weeks of treatment before the operation, the goitre did not apparently increase much in size, but there began to be obstruction to respiration, and marked paroxysmal dyspnœa, chiefly at night In the early morning of the 24th of March, I was hastily called, and found my patient had barely escaped death in one of these paroxysms The parents, indeed, supposed at one time that she was dead I learned that these paroxysms had been gradually increasing in severity for several nights preceding, and that she had not been able to sleep recumbent The voice was stridulous, and there was decided lividity during the height of the paroxysms There was decided obstruction to both inspiration and expiration, and the usual sinking in of the soft parts of the thoracic walls on inspiration I was soon convinced that the patient could not safely pass through another night without relief, and decided upon tracheotomy Drs A B Strong and J D Skeer were called in, and fully concurred in the necessity for the operation In the hope that the obstruction to respiration was largely due to spasm from pressure or irritation of the laryngeal nerves, and in view of the difficulties that were likely to be met with in the low operation, it was decided first to make an opening above the isthmus I must give credit to Dr Skeer, however, by stating here that he did not fully endorse this proceeding The patient being etherized, I made an opening through the crico-thyroid membrane and the cricoid cartilage, an assistant making traction downward on the upper border of the isthmus, which was in the way A tube was inserted, but the dyspnœa was not relieved I immediately proceeded to open the trachea below, and in doing so encountered, in an exaggerated degree, a combination of all the difficulties we are ever liable to meet with in this operation The trachea recedes from the surface as it passes downward, until at the sternal notch it is nearly an inch and a half (Quain) from the surface, normally in the adult, but the distance, of course, was increased by the thickened isthmus in this case

There was absolutely no space for an opening between the sternum and the isthmus, except as the latter was pulled upward out of the way with a blunt hook On this account, the external wound could not be increased in length to correspond with its depth There were large turgid veins crowded together and necessarily embarrassing hæmorrhage, and before the operation was completed enough blood entered the trachea to seriously compromise the patient's chances

The next difficulty was an unusual one The trachea was found to collapse, completely flattening from side to side with each inspiratory effort This unexpected condition materially retarded my efforts to expose and incise the trachea and maintain the opening after it was made, so as finally to get the point of the tube in the incision The crowning trouble, however, was one of simple physics, best illustrated by trying to put a curved pin through a straight auger hole The upper or outer end of the tube, in trying to introduce it, would impinge against the anterior surface of the sternum, and thus prevent the inner end from reaching down far enough to enter the trachea By using some force, and raising the trachea toward the surface, the tube was finally inserted, but with the outer end buried in the wound Fortunately, my tube had a small, round neck shield, which permitted of this During all these steps of the operation, the patient's condition was such as to call for the greatest haste for its completion, as respiration was suspended a number of times completely, and it seemed at the time hopelessly The patient's life hung in a balance for several hours, and it would be tedious to give an account of all the vicissitudes and narrow escapes of the first five or six days succeeding the operation

The ordinary trachea tube proved to be wholly inadequate for emergencies like this, and indeed I believe it to be unfit for any case where the wound is either very deep or very shallow I exhausted all resources trying to get a tube of sufficient length and proper curve, but failed In twenty-four hours, however, it was absolutely necessary to remove the tube first inserted The swelling, still increasing, had already buried the outer end so deeply that it was becoming a source of danger, and the inner tube could no longer be reinserted after removing it to free it from the accumulation of mucus To tide over this emergency, I improvised a tube from a No 12 (English) silver catheter by cutting off the ends at the proper points This being tied in with tapes, proved an admirable device, so far as the length and curve were concerned, but on account of its small calibre and the rapid accumulations of mucus, it required frequent removal to prevent obstruction

A device which I found useful, and which became indispensable in aiding the frequent reintroduction of this tube, is worthy of mention It consisted of a small wire bent on itself in the middle, so that the two extremities were parallel, then curving these to correspond with the inferior surface of the wound, and making a slightly hooked extremity of the loop, which was to be placed in the lower angle of the tracheal wound, the end of the tube was made to glide along the parallel wires Without some aid of this kind, this provisional tube would have been useless

As it seemed likely that the patient would need a tube for some time, I set about devising an instrument that would fulfill the requirements of the case In this I had the valuable assistance of Dr Strong The result was the tube which you now see *in situ*, and which the patient has worn for two months with perfect comfort and safety It is a modification of the tube devised by A E Durham, of London, "who has made a very important advance in this department of mechanical surgery"

The distinctive features of the Durham tube are, first, that instead of being curved, it is right-angled with the angle rounded off, the inner or tracheal portion being short, and the outer or horizontal arm long, and, second, the neck plate or shield is made to slide up and down on the tube, and is secured by a binding screw at the point we desire, in adaptation to the variation in the depth of the wound in the same patient, or in different patients The inner tube is made up of segments jointed together (lobster-tailed), as it must be for any tube which is not a perfect arc

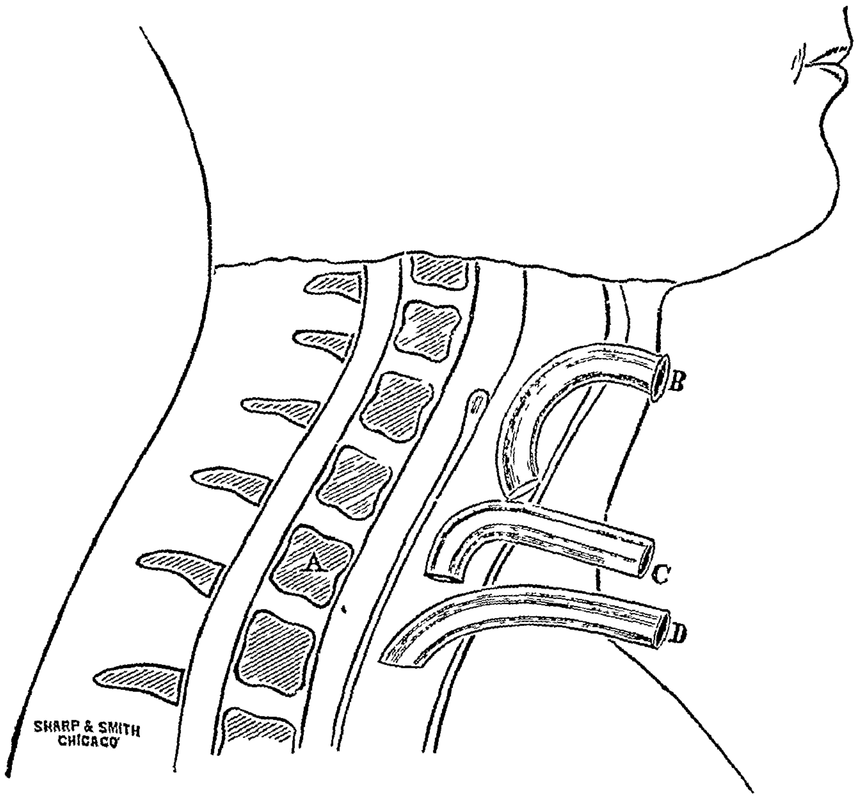
With it, as found in the shops, there comes also a jointed pilot or obturator to render it more easy of introduction

Now this instrument would have answered the purpose in my case if it were possible to introduce it, but it is a physical impossibility to insert the Durham tube with its short, inner arm and right angle through a deep, narrow wound I was not fully convinced of this until I made the effort And besides the axis of the tracheal portion does not correspond with the axis of the trachea at this point, although it does so, nearly, at all points above this

The essential modification of the Durham tube, which I have made, is in the shape The outer or horizontal portion is long and straight, but instead of the angle there is a curve, which, however, is not a perfect arc, but it is the only shape which approximately harmonizes with the anatomical relations of the trachea at this part of the neck, and at the same time makes it possible of introduction I know that only those who have encountered in some degree the kind of embarrassments this case presented, can fully appreciate the advantages of this modification To others it may seem unimportant The only valid objection that has been urged against the Durham tube is that the segments are liable to become detached and pass down the trachea I had this defect remedied by having the tip of the outer tube made slightly conical, and a slight "swell" above the middle of the lower segment, so that if it should become detached it could not pass through I have also discarded the metallic, lobster tailed pilot, and substituted one of soft rubber, made pervious (See illustration)

I think the advantages are obvious in having the pilot hollow, through which a small amount of air can pass while the instrument is being introduced I would like to suggest to the instrument makers that all forms of the Durham instrument be made with the rubber pilot, for while there would be nothing lost in efficiency the cost would be materially reduced I believe the chief reason why this instrument has not come into more general use is because it is relatively expensive If the instrument makers will adopt the suggestion I have made—to substitute the pervious rubber pilot for the metallic impervious one in this tube—they will do the profession a good service At least this modification should be adopted so far as to afford a choice between the two

Messrs Sharp & Smith, of this city, have adopted these suggestions in these tubes, which I exhibit here



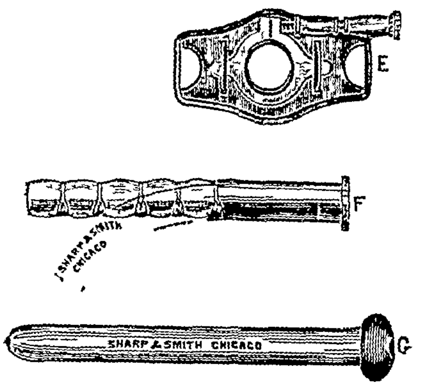


Diagram showing the Increasing Depth of the Trachea from the Surface of the Neck from above downwards in the Normal Condition of the parts and also, the Tubes described in the Paper and their adaptation to the Trachea when *in situ*

A, body of first dorsal vertebra the episternal notch on which *D* lies being opposite the middle of the second *B* illustrates the faulty position which the inner end of the quarter-circle tube assumes in most casesd *C*, the Durhem tube *D*, the modified tube describee in the paper for low tracheotomy, especially when thd wound is deep and narrow *E* adjustable neck shiel for *C* and *D*, but recommended for the quarter circle tube as well, which would make that shape much less objecionable *F*, jointed inner tube, for *C* and *D* *G*, a hollow, soft rubber obturator, recommended as a cheap but efficient substitute for the jointed metal obturator of the Durham tube, or any of its modifications, and suitable for tubes of any shape

The tubes in common use, as all know, are made after the pattern of a quarter of a circle, with almost no variation in length or curve If the trachea were always of a certain fixed depth from the surface, the quarter-circle tube would approximately fulfill the requirements, and it seems to be devised on the theory that there is no variation in the depth of these wounds But we know the great variations of depth at different times in the same case, as well as in different patients When the neck shield is secured against the surface of the neck, as it must be to maintain the tube in position, the inner end in one case would be pushed too far into the trachea In another case, it would not reach far enough to be secure, being easily dislodged by increase of swelling, while in nearly all cases the opening in the lower end, instead of looking downward, looks more or less toward the anterior tracheal wall so as to be occluded either wholly or in part These imperfections, which are inherent in any tube with a fixed neck shield, are happily overcome in the Durham instrument, in which the axis of the tracheal portion is straight and corresponds with the axis of the trachea itself, and what is equally important, this inner end is placed where we desire it, and there secured by moving the adjustable neck shield up or down, in adaptation to the thickness of the tissue at the time of its first introduction, or as they vary from day to day

I think it will be found, therefore, by all who have to do with tracheotomy tubes, that the Durham instrument, with some of its modifications, is the best yet devised, and the only one constructed on correct principles

It is a pertinent and practical question why a goitre of this size should interfere with respiration, for, as compared with the average goitre which we meet with in practice, this is not a large one The rule is, even in those cases in which the gland is enormously enlarged, that there is no obstruction to respiration So that size, as such, is not a factor in causing compression of the air tube ordinarily We know as a clinical fact that in acute goitre, where a considerable increase in the gland takes place in a few days, there is generally more or less dyspnœa But in this patient the gland had been gradually increasing in size for a period of four months before there was any noticeable dyspnœa I recall that when I was a medical student, Prof Frank H Hamilton related in one of his lectures to the class the particulars of a case of threatened suffocation from goitre, in which a post-mortem examination showed that a part of the isthmus was behind the trachea, which was compressed between the two portions An account of this case is given in Hamilton's Principles and Practice of Surgery Some works on anatomy I find allude to this anomaly, and there have been found a few cases where the entire isthmus was placed behind the trachea I think it probable that it is in some such anomalous disposition of thyroid tissue that we will find the explanation of the obstruction in this case, and in all those cases where neither the rapidity nor the size of the enlargement is sufficient to account for the conditions

---

PNEUMONIA IN HIGH ALTITUDES AND ITS TREATMENT WITH JABORANDI

BY J W BROWN, M D

The greater prevalence of pneumonia in proportion to the population and its much higher rate of mortality in mountain attitudes, than at the average elevation of the earth's surface, set the writer, about six years ago, to seek about for a plan of therapeutics of greater efficiency than that generally practiced and approved About that time jaborandi came into use, and there were notices in the medical journals of its efficacy in the treatment of dropsies by virtue of its peculiarly powerful influence on the sudoriparous glands Its wonderful diaphoretic power pointed it out to the writer as being possibly a useful agent in the treatment of pneumonia in its early or formative stage, with the object in view that by its means an abortion of the disease might be effected by limiting the effusion, and thus averting the perils of a fully developed pneumonia

An immediate trial of the drug seemed to confirm the supposition, and an invariable use of it for the last five years in the formative stage of pneumonia has been productive of such extraordinarily beneficial results, apparently, that the writer is induced to present the experience and the method to the attention of the medical profession, asking their indulgence to the extent of first putting the method to a fair trial and then approving or condemning as the results may warrant

There is nothing of originality claimed in this practice by the writer, for he is fully conscious that the result of the action of the drug is identical with the result of the action of the steam-bath or sweat bath practiced by Thompson and others with the same end in view—the abortion of pneumonia in its formative stage This resort to an almost obsolete method has been the outcome of necessity in an endeavor to obviate the almost certain death that follows upon a fully developed pneumonia in the altitude of the writer's practice, viz An elevation ranging from eight to twelve thousand feet above the level of the sea, in the San Juan mountains An exceedingly high rate of morality, and a greater prevalence of the disorder in proportion to the population than at lower levels, accords, we believe, with the experience of every practitioner of medicine in the mountain altitudes, and a firm conviction of the efficiency of this method as a result of five years' experience with it has led the writer to lay this report before the medical profession, sincerely believing that its general adoption will materially diminish the mortality resulting from simple pneumonia, whether occurring in mountain altitudes or at the level of the sea

We give a few illustrative cases

Case No 1 Mrs S, aged 30, merchant's wife Had had pneumonia according to her own account, several times before at Del Norte, about seven thousand feet above sea-level Had probably had pneumonia before, because she detailed the symptoms of pneumonia of her own accord, viz A chill, with a sense of shortness of breath, followed by pain in the chest, cough, bloody expectoration, fever, prostration, and three or four weeks' sickness, she being at the point of death part of the time, and all the while under the care of a regular practitioner About five years ago was called to see her, found her in a rigor which was very marked Her face was cyanosed, extremities cold, she was shaking from head to foot, and her teeth were chattering as though she had an ague, and she complained of a shortness of breath She said "I am going to have pneumonia, I recognize it and I am afraid of the result" She was then living 9,400 feet above the sea Ordered her put to bed immediately and prescribed

℞	Ext jaborandi fl	℥iv
	Spts ammon aromat	♏40
	Syrupi simplicis	℥iv

M S One teaspoonful every two or three hours to induce profuse perspiration

She was put to bed, covered heavily with blankets, surrounded with hot irons wrapped in wet cloths, the irons being placed close to her body and the mixture administered as directed In about twenty minutes she commenced to perspire profusely, and the sweating was maintained at its highest pitch for about six hours Her bedding and clothing were then changed, her body wiped dry and fifteen drops of the mixture were administered sufficiently often during the night to keep her skin moist The next morning she got up at her usual time and resumed her household duties During the day she expectorated a small quantity of pneumonic sputum and complained of a slight feeling of soreness in the lower lobe of the right lung, but recovery was almost immediate She did not go to bed again on account of this sickness and she had no further medication on that account

Case No 2 J B, a miner, aged 54 Lived in a miner's cabin about four miles out of town, and at an elevation of about 10,000 feet On inquiry found that he had the symptoms of commencing pneumonia Prescribed the mixture of the above prescription, and gave directions as in the preceding case The next day the brother reported the patient better in some respects but worse in others He said the patient had retention of urine Went up to see him and found him on his knees in bed vainly trying to void his urine into a tin cup Introduced a catheter and found the bladder almost completely empty Ordered cold water to be drank in plentiful quantity, the patient having abstained from drinking water for fear of aggravating the supposed retention of urine He expectorated pneumonic sputa for two or three days, but within a week he resumed his work. In this case the sweating was so extreme that the skin had temporarily almost entirely usurped the function of the kidneys in the elimination of water, and the small quantity of urine in the bladder—a few drops only—was very acrid and irritating The kidneys resumed their function in a few hours

CASE No 3 J K , aged 24, a miner Lived at Ophir, thirteen miles away, across a mountain range, and at an elevation of 10,000 feet He was taken with a chill at four o'clock in the morning I arrived at his bedside at half-past four o'clock in the afternoon, so that the disease had a start of twelve hours and a half From description given by messenger, a diagnosis of pneumonia was made out The patient was in bed Face was dull and leaden in color, he had fever, cough, pain in the right lung, and a sense of shortness of breath, and the floor near the head of the bed was covered with bloody expectoration The floor was spattered with pneumonic sputa all over an area three or four feet in extent in all directions Physical examination showed a dullness in the lower part of right lung, with subcrepitant râles This was a case of plastic pneumonia beyond the shadow of a doubt, and it had a start of twelve and a half hours He was treated in the same manner as the two preceding cases In a quarter of an hour beads of sweat stood out on his forehead, and the patient was informed of the certainty of a speedy recovery

As the sweating progressed, he experienced proportionate relief The sweating was continued at the highest pitch for nearly eight hours Ordered a diminished dose of the mixture, continued for two or three days, gave general directions for his further management, and dismissed him with orders to report if necessary In a week he resumed his work, having made a complete recovery

CASE No 4 J C , saloonkeeper, age 24 Had had pneumonia two years previously at Leadville, and was confined to his bed three weeks, being very dangerously ill, according to his own statement, most of the time He spoke very flatteringly of the physician in charge, on account of the good care rendered, and expressed himself as very lucky that he finally recovered, the prevalence of the disease and the rate of mortality being exceedingly great at that time at Leadville Was called to see him on a Sunday afternoon, at half-past three He had been taken with a chill at seven o'clock in the morning of the same day, so that the disease had a start of eight hours and a half His pulse was full and bounding, expectoration profuse and typically pneumonic, there were fever, a dull, leaden face, pain in the right lung, cough, and a sense of a want of breath Examination gave the physical signs of pneumonia He said it was the same thing he had at Leadville He was treated in the same way as the preceding cases, with the same exceedingly profuse diaphoresis as a result, and the same relief He remained in bed till the following Thursday morning, when he got up at the usual time and resumed his regular occupation He was dismissed on Thursday morning without further treatment, and two days after was apparently well Other cases may be given, and some who have walked the street within two days expectorating pneumonic sputa, after being subjected to the jaborandi sweat-bath ordeal, without relapse or further inconvenience, convalescence continuing to perfect recovery in a few days thereafter

These cases are but examples of the usual behavior of pneumonia treated by the jaborandi method, in the formative stage, so far as the experience of the writer goes, during the last five years, so that he feels compelled to advocate a more general trial of the method, having had two cases only of death from this disease in five years, one being a case of neglected pneumonia, which had developed to the involvement of two-thirds of the right lung in pneumonic solidification, death taking place suddenly on the day after the first visit and apparently from heart clot, the second case being that of an old man whose constitution was already shattered with hard drinking, and in whom the disease, if it were pneumonia, developed insidiously and resembled as much a hæmorrhage as pneumonia, symptoms were so anomalous

In the practice of the writer, he feels that pneumonia has lost its terrors even in these high mountain altitudes, whereas before this practice the mortality was great and the doctor overwhelmed with a sense of helplessness A case of simple pneumonia that would recover without any care, other than that of simple hygienic management, at sea-level, seemed, in these altitudes, to be almost necessarily fatal, and recovery from double pneumonia an impossibility The only safe way in mountain altitudes is to abort the disease early, before the advent of symptoms indicating asthenia, and this can be done at any time previous to the appearance of asthenic symptoms by the simple method detailed herein, that is to say, limitatioin the extent of the solidification may at any time be effected before symptoms of asthenia make their appearance, so that as small a portion of a lung as possible may be rendered useless by solidification

The excessive mortality in pneumonia at mountain altitudes, over that at the average level of the earth's surface, seems to be due to the rarefied condition of the atmosphere mainly, its chemical composition being the same as everywhere else in open country, as shown by chemical analysis of three specimens, one of which only showed a trace of ozone

Exhaustion seems to take more rapidly on this account, due probably to a deprivation of oxygen At 10,000 feet, a volume of air of sea level density expands into about one and one-half volumes, so that a man in health needs to breathe a quantity of air greater in volume by one half, in order that the tissues of the body at large may be supplied with the requisite quantity of oxygen Hence, probably, the greater gravity in mountain altitudes in case in which a considerable portion of a lung becomes solidified In an inflammation of lung tissue there seems, also, to be a greater rapidity in the spread of the inflammatory process to adjacent lung tissue, probably owing to increased functionation, and hence the necessity of a more active treatment to stay the inflammatory process and effect resolution That a pneumonia may be aborted the writer has no doubt, judging from these results, however crude the experiments may be, and that the duration of the disease is in ratio with the extent of the solidification, and inversely, also that the extent of the solidification bears a relationship to the time elapsing between the initiatory chill and the establishment of a thorough derivation by profuse diaphoresis

It would seem, also, that the pathological condition is a simple inflammation independent of zymotic influence, as the remedial agent in its action is purely physiological, a derivative influence only being exerted from the lung tissue to the cells of the sudoriparous glands,—otherwise, on the cessation of the physiological action of the drug, the zymotic influence still persisting, the pathological process ought again to be awakened

The method described is inapplicable after the appearance of asthenic symptoms, because the mischief sought to be averted is already in existence and is the cause of the asthenia, viz a fully developed pneumonic solidification If it is now too late, the only resort remaining is the method of support and hope, both together, in these mountain heights at least, being inadequate to the making of a lung largely hepatized to breathe a sufficiency of oxygen for the needs of the economy, when in its full capacity this is about all that it can do

The writer has taken advantage of the sudorific power of jaborandi in the treatment of other inflammatory affections, and notably in the treatment of quinzy and bronchitis, and with results similar to those obtained in the treatment of pneumonia But in all instances it is a remedy only in the formative stage

SILVERTON, COL, Feb 14, 1885

MEDICAL PROGRESS

OBSTETRICS AND GYNÆCOLOGY.

LOCAL TEMPERATURE OF THE BREAST AFTER DELIVERY —M Chatelet (*Paris Medical*) has studied the local temperature of the breast at the time of the secretion of milk, and finds that it results in an elevation of temperature to the extent of two or even three degrees, that there exists an evident relationship between the temperature of the breast and the secretion of milk, the temperature rising as the secretion becomes more abundant, that, on the second or third day after delivery, the local temperature of the breast reaches and passes 36° C, and that if it remains at that register for the first eight or nine days of lactation the milk is sure to be abundant, that the secretion of milk will be but slight if the temperature remains below 36°, or does not retain that register, that the secretion of the milk has no influence on the general temperature, and that milk-fever does not exist, and finally, that the general temperature has a marked influence on the local temperature of the breasts

TRAUMATIC TUBERCULAR PLEURITIS —Prof von Bamberger (*Wiener medizinische Wochenschrift*, *Med Times*) gives the case of a man, aged 43, a confirmed drinker, who was struck on the left side of the thorax by a wheel Pain, cough, and other symptoms of pleuritis rapidly showed themselves The patient, in whom no inheritance of tubercle could be traced, presented when first examined all the physical signs of left-side pleuritic effusion The sputa and blood were carefully examined, but no trace of bacilli could be discovered The case progressed unfavorably throughout, and fever, cough, and dyspnœa became daily worse Thoracentesis was delayed by the patient's obstinacy, till a month's illness had materially depressed his strength and Cheyne-Stokes respiration had set in The operation gave but little relief, and death ensued from œdema of the lungs The autopsy performed by Professor Kundrat proved the existence of extensive diffusion into the left pleural cavity, the walls of which were lined by a thick false membrane studded with nodules of tubercles of the size of millet seeds The left lung was completely compressed, but no tubercles could be discovered within it, nor were they to be found in any of the other organs of the body By the microscope the nodules in the thickened pleura were found to contain numerous bacilli, indistinguishable in form and character from those described by Koch, but similar investigation of the pulmonary and other tissues of the body failed to discover a trace of them elsewhere If it be admitted that the bacilli in such a case as this form the determining cause of the disease, it only remains to be decided how the bacilli obtained access to the affected part One theory propagated by Baumgartner suggests the possibility that a real physical inheritance of the virus has taken place, and that the poison lies dormant in the body until favorable conditions for its development present themselves Another view, perhaps more easy of acceptance, regards the general circulation as the natural channel for the distribution of the bacilli, and the white corpuscles as the bearers of them An apparently primary tubercular affection such as this case exemplifies is occasionally to be noted in the long bones, in which also the presence of bacilli has been more easily demonstrated than explained

MEDICINE.

ON GUMMATA OF THE SKIN —According to Balzer (*Revue de Medicine*, *Jour de Medicine*) the specific character of the products of inflammation is not distinguishable by the anatomical form, the differences in these forms occur, on the contrary, in their modes of evolution

The process of evolution of the gummata comprises three stages

1 Inflammatory stage formation of primitive gummous nodules about the vessels (period of crudeness of the gummata), elongated cylinders composed of embryonic cells more or less developed (lymphoid or epitheloid elements) envelop the vessels, they result from an inflammation of the vascular walls The vessels are still permeable At this time the lesion is still curable,

2 Stage of degeneration vascular obliteration, necrosis with consecutive coagulation, granular degeneration, formation of a caseous deposit The degeneration commences at the periphery of the nodules and follows the contiguous vessel in a centripetal course The degeneration is in part of a fatty nature, and partly of an indefinable nature (granulations that are insoluble in ether, and not colored by osmic acid) In the caseous masses the presence of elastic granules indicates the destruction of elastic

fibres, and they are detected by picric acid, but they soon lose their micro-chemical characteristics and are confounded with the other granulations,

3 The evolution terminates in two different ways (*a*) encysting of the caseous deposit, which is enveloped by a sclerous zone, increasing until the disappearance of the deposit by absorption, (*b*) extensive advance of the degeneration, destruction of the epidermis, ulceration and progressive elimination of the gummous deposit

Icterus Produced in the Course of a Few Hours by Nervous Irritation —Dr H Rendu (*France Medicale, Jour de Med et de Chir*) relates the case of a woman 25 years of age, who had been treated in his hospital service for puerperal peritonitis During her convalescence, while her general condition appeared to be good, she was affected with retention of urine The student who attempted to use the catheter made several ineffectual efforts, but was obliged to desist on account of a sort of nervous crisis which his manipulations produced Three-quarters of an hour later, when he returned to the ward, he was astonished at seeing his patient manifestly jaundiced (she had a very clear skin previously) As he was about to attempt catheterism again the patient, still very nervous, urinated spontaneously—the urine being of a deep brown color, and evidently containing biliary pigment This occurred at 11 30 A M At 1 P M the yellow color was marked not only in the conjunctivæ, but also all over the skin, being most pronounced on the abdomen and trunk, and a little less so on the extremities

On the following day the jaundiced appearance was as decided as during the most intense and prolonged cases of hepatic colic The urine looked like brown beer, and gave a green color on the addition of nitric acid The stools were of the greyish, clayey character, as when deprived of bile The pulse was normal—no prurigo, no nervous trouble, no hæmorrhagic tendency, tongue clear, marked thirst, no want of appetite, ate but little, no pain over nor enlargement of liver, no abnormal sensibility at the epigastrium

For two days the icterus retained its maximum of intensity The third day it commenced to decline, and the stools took on a little color, the urine remaining dark The fourth day gave no trace of the jaundice externally, only the urine was a little dark in color and responded to the nitric acid test On the fifth day there was no evidence whatever of the recurrence of jaundice

Osmic Acid in Sciatica —Mr James Mercer reports in the *Lancet* the results of his practice with this drug in eighteen cases, treated at the Bath Mineral Water Hospital He claims that only about twenty-five per cent remain of the cases admitted as not benefited by the waters, and it is to this twenty-five per cent that he applies this treatment The patients' ages varied from eighteen to sixty-five In twelve cases he succeeded in giving them absolute relief for a period of three weeks The number of injections varied from one to four In six he gave temporary relief The injections were as many as twelve in one case, and they obtained more comfort by its use than even by hypodermic injections of morphia He used a one per cent solution, injecting deeply over the sciatic nerve, at a point midway between the tuber ischii and trochanter major, three to five minims of the solution It produced no constitutional effects, but locally at the seat of puncture the patient invariably complained of a numb feeling, which, however, was transient In some cases the effect was marvellous, the patient being able after a short time to stand on the affected side, which he had been unable to do for years

On the Elimination of Phosphoric Acid by the Urine in Mental Diseases —M A Lailler (*Annales des Maladies des Organes Genito-Urinaires*) gives the following as the result of his researches

1 In acute delirium and in acute mania, phosphoric acid and urea are eliminated in notable excess

2 In mania with excitement, phosphoric acid is eliminated in slight excess, that of urea is normal

3 In simple mania the urine is physiologically normal

4 In melancholia in the acute stage or with excitation, there is a notable increase in the elimination of urea, and a slight increase in the elimination of phosphoric acid

5 In melancholia without excitation, there is no increase over the physiological quantity of phosphoric acid eliminated in urea

6 In general paralysis, the excretion of phosphoric acid and of urea is in close relation to the multiple morbid conditions characteristic of that disease

7 In epilepsy the urine at the time of the crises, or immediately afterwards, contained a markedly increased proportion of phosphoric acid, and a moderately increased proportion of urea, when the attacks succeed each other rapidly there is an exaggerated amount of both phosphoric acid and urea, in the intervals of the attacks the urine is normal

Auscultation of the Œsophagus in Deglutition and in Pathological Conditions —A Baretz (*Revue de Medecine, Jour de Med*) considers that In the normal state, the sounds of deglutition are perceptible by auscultation in the interscapular region, and seem to be a little more intense to the left than to the right of the vertebral column

In certain pathological conditions the intensity of the sounds of deglutition seems to extend in a greater degree to one side or the other of the vertebral column Among these pathological conditions the most noteworthy were First, the tuberculous induration of the apex of the lungs Second, the tracheo-bronchial ganglionic engorgement In these cases the intensity of the sounds of deglutition is most pronounced on the side where the lesion exists or predominates

At other times the modification influences not only the intensity, but also the quality of the sounds of deglutition Thus, in a case of pleuritic effusion, the sounds of deglutition on the corresponding side partake of the quality of the pleuritic souffle

Baretz considers that the study of the sounds of deglutition as now applied to the diagnosis of the seat of a lesion of the œsophagus (narrowing, for example) might also be applied in certain cases in determining the exact seat of a pulmonary lesion

The Diaphoretic Treatment of Puerperal Eclampsia by Means of Hot Baths —Brens (*Archiv f Gynak* , *Edin Med J*), has now reported two sets of cases placed under this treatment The first set included six cases, with five recoveries and one death, the second set includes eleven cases with one death The treatment consisted in placing the patient in a bath (38° C), raising the temperature gradually, then wrapping her in blankets, thus securing profuse diaphoresis Of the eleven cases four had convulsions at the beginning of labor, two during the first stage, one during delivery, and four after In the majority of cases the eclamptic seizures were severe In the fatal case the issue was more probably dependent on peritonitis, possibly septic, than on the convulsions The two series together, then, afford a total of seventeen cases, with but two deaths—one of these latter not from convulsions In eclamptic seizures the danger to life depends only indirectly on the convulsions The main danger lies in the altered characteristic of the blood—hydræmia—and the consequent albuminuria and anasarea These accompaniments of Bright's can obviously best be met by profuse diaphoresis, a treatment which, while it can have little effect toward curing the kidney trouble, undoubtedly relieves the symptoms which are threatening the life of the sufferer. From the use of this hot-bath treatment Brens has seen nothing but good effects It is not apt to cause either abortion, or premature labor, or hæmorrhage, on the contrary, he would advise the use of hot baths at any time of pregnancy when the appearance of albumen in the urine and coexisting œdema causes apprehension of ill, indeed, they are indicated as a prophylactic measure A striking case is recorded, where a patient, æt 26, in her first pregnancy, highly dropsical, with a large percentage of albumen in the urine, was subjected to the hot-bath treatment at the eighth month, went to term, was delivered of a child weighing 2,700 gm , received during this interval forty-five baths with positive good effects, both as concerned her own condition, the continuation of the pregnancy, and the safety of the child This treatment answers when eclampsia exists, and also in those cases where the occurrence of the eclampsia may be apprehended

Treatment of Earache —M Moure (*Jour de Med de Bordeaux*, *Jour de Med et de Chir*) uses habitually a combination of atropia with morphia to quiet the pains of earache, giving relief to otalgia and to cases of subacute otitis of the tympanum and of the Eustachian tube, particularly in children He prefers a solution of morphia to instillations of oil, laudanum and ether, these substances having the effect of producing a traumatic meningitis and sometimes graver lesions He prescribes Sulphate of atropia, 2 to 5 centigrammes, chlorhydrate of morphia, 5 centigrammes, neutral glycerine, 15 grammes, on cotton wool at the external auditory meatus, and, when necessary, a drop or two by instillation night and morning into the auditory canal This will relieve external otitis and furunculous otitis

Disease from Bichromate of Potassa —Dr B W Richardson, in *The Asclepiad*, gives a plate showing the diseased influence of this drug upon the hands in an admirable manner, and gives an account of its mode of action It seems that in transferring the neutral chromate of potassa by means of acid into the bichromate, the vapor arising carries with it an infinite number of pulverized particles of the bichromate, which, inspired in abundance, give to the palate a bitter and very disagreeable taste If the respiration be made by the nose the particles are dissolved in the secretion of the membrane of the septum of the nose, creating a violent pricking, suffusion of tears, and irresistible sneezing In time, the membrane begins to be thrown off, and portions of it are carried into the handkerchief used in blowing the nose This process goes on so rapidly that after a period of six or eight days the septum becomes thin, is permeated with openings, and is ultimately detached altogether At this point all the symptoms cease, and the workman scarcely notices the loss of the nasal partition This process of ulceration does not occur in those who take snuff In these, owing to the layer of powdered tobacco which covers the membrane, and the frequent use of the handkerchief, the evil is removed, or rather prevented It is the cartilaginous portion of the structure that is specially attacked

On the skin, in its normal state, the epidermis being intact, the bichromate exerts no baneful influence, the hand may be plunged into a concentrated and hot solution of the salt, and remain covered with it for an entire day without effect, but if the skin is torn or abraded, a sharp pain is felt, the cutaneous tissue is decomposed, and violent inflammation is established These symptoms are accompanied with intense pain, especially in winter, when the cold is severe The action of the salt does not cease until the cauterization has penetrated to the bone Internally, in a small dose, a few centigrammes, the bichromate acts as a purgative, in larger doses, say of one gramme, it acts as a poison In the large doses it produces colic and purging, but no vomiting In one manufactory certain of the workmen placed some bichromate of potassa in a barrel of cider as a joke All who drank of it were affected with severe colic and diarrhœa

Dr Richardson gives five cases of workmen in business where the bichromate is used, and as a weak watery solution of five to six per cent of the salt, where the hands and forearms were the parts most affected and as if affected with acute eczema The symptoms as described by a sufferer are as follows "The first symptoms of local poisoning are heat, itching, and tingling upon the ends and middle joints of the fingers, which, when examined, are found to be covered with minute, irregular red patches, upon which are numerous small elevations clustered together In the course of a day or so these enlarge to the size of a small bead, and are filled with a limpid fluid In a short time these clusters run into each other, forming large blisters, which dry and crack open, causing the most acute pain and itching At this stage pustules begin to form over the body, mainly down the spine, on the neck, left side, arms and ankles, accompanied with considerable constitutional affection, such as sickness, headache, thirst, fever, sleeplessness, and loss of appetite " The eruption did not always partake of the character of eczema, but in one case bore a close resemblance to pitzriaris rubra

As to treatment, the application, while exposed, of a wet sponge before the nostrils appeared to be advantageous When the skin was abraded, and the chromate had produced ulceration, it was the best treatment to wash thoroughly with a feeble alkaline water, then, if inflammatory action followed, to poultice, and afterward to apply freely sub-acetate of lead in solution Abstinence from beer, spirits, coffee, potatoes, brown meats, salt fish, sugar, and tobacco One drachm of liquor potassa in a cupful of barley water thrice daily, before meals, for five or six days, after which three times daily of tr serpentaria one drachm, with five drops of laudanum When the patches begin to heal, resin ointment locally, and a mixture of ammonio citrate of iron, with iodide of potassium and bromide of ammonium in solution with camphor water Washing the hands in ammonia does no good, a solution of bichromate, rendered perfectly alkaline with ammonia, poisons quicker than an acid or neutral solution Dr Richardson recommends the wearing of a mask and impermeable gloves while at work

His theory of the mode of action of this agent is, that it acts upon the gelatinous structures of the body It changes their molecular condition, and renders them insoluble That leads to an arrest in the living dialysis and in the transudation of fluid The arrest leads, in turn, to perversion of function, to congestion, and to all the subsequent phenomena

Morphia in the Urine of a Morphine Habitue —Dr B W Richardson, in his *Asclepiad*, gives the case of a man, aged 47 years, tall, plethoric and ruddy, who has been addicted to morphia-taking for the past ten years When first seen he was taking thirty-eight grains daily Twelve ounces of fresh urine, after the injestion of thirty six grains, yielded morphine equivalent to 1 2 grains of morphia acetas The morphine was satisfactorily identified by Mr A Winter-Blyth, turned into the crystalline hydriodate, and gave the usual reaction with iodic acid A few days later, after the injestion of twenty-one grains, the urine yielded the equivalent of one grain of the salt Still later, the quantity injected being reduced to six and a half grains, the urine yielded 0 18 grain of the salt

A Simple Disinfecting Lamp —Take an earthenware or metal lamp, fit it up with the cotton wick in the usual way, and then charge it with a mixture of equal parts of common benzoline and of carbon bisulphide The lamp so formed is lighted in the usual way, and gives off when burning free quantities of sulphurous acid The object of adding the benzoline is to give steadiness to the liquid during the process of burning —*Dr B W Richardson in his Asclepiad*

SURGERY.

Effect Produced by the Introduction of a Bed bug into the Ear — Dr Grand (*La Loire Médicale, Paris Medical*) gives the case of a patient who was awakened at night by an intense pain in the left ear She felt something running at the same time in the auditory canal, and supposed that some insect had entered there She filled her ear immediately with warm water, and in about half an hour the pain was lessened, and the movements which were felt ceased entirely However, a dull pain with deafness remained, accordingly, on the following day, by the advice of a friend, she dropped several drops of the essence of peppermint into the ear Immediately there followed an intolerable pain which lasted two hours When seen by the doctor on the third day, she complained of frequent severe lancinating pains in the ear, of deafness and of noises The watch could not be heard to tick when applied against the affected ear, while on the sound side it could be heard at a distance of forty centimetres On illuminating the interior of the auditory canal, a dead bed-bug was seen distinctly upon the tympanum, and a slight injection of warm water dislodged it The tympanum was markedly red and thickened throughout its extent It was impossible to examine it in detail, except attachment of the external apophysis of the malleus It seemed to be slightly more concave than is normal There was then an acute myringitis produced both by the essence of peppermint injection and by the presence of the bed-bug There are several observations on record where bed bugs have passed into the ear and produced acute pain by sucking the blood from the membrane of the tympanum This pain is infinitely more violent than that produced by the movements of the feet of other insects The inflammation of the tympanum was relieved in eight or ten days, the hearing returning to its normal condition The treatment consisted in the use of insufflations by Politzer's bag, and slight applications to the tympanum of boracic acid and vaseline

A Perineal Calculus —Dr Sarget de Orihuela records (*Union de las Ciencias Medicas, Gaz hebd des Sciences Med*) the case of a laborer who suffered for two years from a tumefaction in the perineal region, which was the cause of sharp pains The patient attributed his difficulty in urinating to the pressure exerted by the tumor upon the urethral canal Several diagnoses had been made, one of a tumor of the prostate, a malignant tumor, and of a phlegmon Direct examination showed an extensive induration from the base of the scrotum to the anterior segment of the anus, of an almost cartilaginous consistency, and the slightest touch produced acute pain Urination was drop by drop and very painful A local application of strong iodine ointment produced increased pain, an increase in the size of the tumor, and resulted in the formation of a point of fluctuation Puncture discharged a large quantity of pus and allowed the passage of the index finger, which encountered a hard, rough foreign body implanted in the peri-urethral tissue, this was removed with the forceps in three fragments, after which the wound cicatrized, but not very firmly, but urination became easy, and the general health was reestablished

As a cause for this deposit it seems that the patient had at one time received a contusion in the perineal region, resulting in the retention of urine for thirty-six hours For fifteen days afterward he suffered from acute pains in that region, which gradually disappeared The calculus was formed mostly of phosphates, of carbonate of lime and organic matters There were also traces of urate of lime

Contusion and Laceration of the Kidney, Recovery —Dr Gelly (*Revue Medicale de l'Est*, *Annales des Maladies des Organes Genito-Urinaires*) describes the case of a man, sixty-two years of age, who was injured by the wheel of a passing carriage, he sustained a fracture of the twelfth rib on the right side, and at the same time the urine was colored by hæmaturia This hæmaturia persisted for five days and then disappeared, to return on the twelfth day in consequence of the getting up and violent sneezing of the patient There was then very acute pain, which was, however, but momentary, and felt in the right renal region The blood was discharged in much greater abundance than at the time of the accident This time the hæmaturia persisted for nine days and then disappeared Eight days later there was retention of urine with persistent straining, which finally yielded to the violent efforts of the patient, and there was an evacuation of a notable quantity of blood which was almost pure, mingled with voluminous clots, and nearly filling a third part of a chamber pot The bladder, which had formed a hard ball in the hypogastric region, became normal and the patient was relieved The hæmaturia diminished rapidly and ceased definitely three days later For some time the patient was kept under the influence of ergot, of injections of ergotine in the renal region, and the sulphuric acid mixture (eau de Rabel), which latter was freely used at first

A month after the last hæmorrhage there was no longer any blood in the urine, nor was any albumen present M Gelly has no doubt but that this was a case of laceration of the kidney He considers the wound of the kidney, while in course of cicatrization, to have been opened the first time from a mechanical cause, and a second time without any appreciable cause It did not definitely cicatrize except by delayed union and a new generation of the lacerated surfaces The precise seat of the laceration remains hypothetical The absence of all tumefaction would indicate a perinephritic discharge, and the laceration probably had its seat near the hilum, directing the blood into the calices and pelvis of the kidney

Cocaine in Rectal Surgery —The *Lancet* gives us a reference to the case reported by Dr Bettelheim, of Vienna, of a man aged seventy four, who had well-marked anginal attacks the result of atheroma of the aorta and ossification of the coronary arteries For some time he had, in addition, complained of rectal and vesical tenesmus Percussion over the bladder showed that it was not dilated, and rectal examination demonstrated the fact that the prostate was much enlarged, and probably the cause of the trouble Cacao butter suppositories were ordered, each containing half a grain of muriate of cocaine One of these was inserted into the rectum at bedtime, and the patient slept well and was not troubled during the night The beneficial effects were apparent the whole of the following day The suppository was not given that evening, and the patient passed an uncomfortable, restless night The next day another suppository was ordered, and acted as well as the first

Injections of Quinine in Urethritis —M Girerd (*Jour de Med et de Chir*) uses the following with success in paludian urethritis

Chlorhydrate of quinine	2 to 4 grammes
Distilled water	300 grammes
Glycerine	50 grammes

This injection, repeated three or four times daily, has always arrested the most rebellious discharge

Weirs (*Gaz hebdomadaire*) uses in true blennorrhagia

Sulphate of quinine	1 gramme
Water	75 grammes
Glycerine	25 grammes
Eau de Rabel (acids sulph alcoholisatum, q s	

Three injections a day of about five grammes Great care must be taken not to interrupt the use of the injections until the discharge has ceased, as, in that case, relapses are frequent

Exfoliation of the Cochlea without Causing Deafness —The Vienna correspondent of the *Lancet* describes a case under the care of Professor Gruber, a lad aged fourteen, who had been ailing for four years, suffering from an old otorrhœa, with polypus of the left ear As the patient experienced great pain, and as paralysis of the left nervus facialis existed, Professor Gruber had no hesitation in entirely removing the polypus, and in so doing came upon the cochlea in a state of necrosis Since the operation the patient has felt better, his pains have ceased, and the paralysis of the nervus facialis has nearly disappeared, but, strange to say, the lad's affected ear has regained its power not only of recognizing sounds, but of distinguishing musical notes

The Professional Lipoma of Prostitutes —Dr Preis (*Weekly Medical Review*) has noticed in 217 prostitutes a sort of lipomatous tumor seated between the sixth and seventh cervical vertebræ over the spinous apophyses These hemispherical tumors are a little firm, elastic, mobile, and not painful He considers them to be due to pressure and friction during coitus, and has not found them in those who are not prostitutes

THE
Journal of the American Medical Association.
PUBLISHED WEEKLY

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information, should be accompanied by the writer s full name and address, although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE, INCLUDING POSTAGE

PER ANNUM IN ADVANCE $5,00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any date The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned When neither is accessible remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 65 RANDOLPH STREET,
CHICAGO ILLINOIS

SATURDAY, MARCH 7, 1885

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION —As the time is near for the next annual meeting of the association, when the board of trustees charged with the publication of this JOURNAL must make arrangements for the future, I regard it as a duty to give all parties interested as accurate information as possible concerning the past progress, present condition and future prospects of the journalistic enterprise I shall do this with no feeling of embarrassment or selfish interest, as I accompanied my letter to the board of trustees accepting a continuance of the editorial office, at its meeting in Washington last May, with the explicit declaration that "under no circumstances" could I extend that continuance beyond the present JOURNAL year, which closes with the current volume, June 30, 1885 Those who originated the policy of changing from the publication of the Transactions, in one annual volume, to that of a weekly journal, claimed three leading and important advantages for the latter method

1 That the reception of a JOURNAL every week containing some part of the doings or papers of the association, and a fair amount of the current items of medical progress in all departments of the profession, would tend strongly to keep up an active interest on the part of each individual member, and induce a much larger proportion of those who once become members to retain such membership by the payment of their annual dues, and the aggregate membership of the association would thereby increase far more rapidly until it should embrace a large proportion of the more active and intelligent members of the profession in all parts of our country

2 That all the proceedings and important papers of each annual meeting would be given to the profession in the columns of such a journal much earlier, and in such installments that even the most busy members would read and profit by them to a much greater degree than when receiving the whole in one volume nine or ten months after their presentation at the annual meetings

3 That the JOURNAL, under proper editorial management and ability, visiting the leading members of the profession in each state every week, would exert an efficient and most important influence in maintaining sound principles of ethics, in hastening the general adoption of a higher standard of education, both literary and professional, in diffusing sound principles of legislation on medical interests, and in promoting universal social unity in the profession

Although less than two years have passed since the first number of the JOURNAL was issued, its effect in retaining and increasing the membership is already perceptible in a marked degree The triennial list of permanent members of the association has been published by the permanent secretary, in 1875, 1878, 1881 and 1884 The lists of the three first periods indicate the progress of membership during the ten years preceding the commencement of the JOURNAL, and that of the last period the progress during the three years embracing the first eighteen months of the publication of the Journal The whole number of names of living members in the list of 1875 is 1,428 The whole number in the list of 1878 is 1,989, being an increase of 187 per annum The whole number in the list of 1881 is 2,403, or a gain of only 138 per annum The whole number in the list of 1884, which includes the first year and a-half of the publication of the JOURNAL, is 3,247, making an increase for the last three years of 281 per annum, or more than double the ratio of increase for the three preceding years The publication of the JOURNAL was commenced in July, 1883, with a list of only about 2,500 members and subscribers On March 1, 1885, the list had increased to 3,887, of whom 3,033 are entered as permanent members of the association and 854 as subscribers The copies to exchanges, advertisers and correspondents aggregate 120, making the present weekly circulation 4,007 The *British Medical Journal* was commenced twenty years since, with a supporting membership of the British Medical Association of little more than 2,000 It has now a supporting membership of about 12,000, being an increase of 500 per annum

If the same ratio of increase exhibited above should be continued, the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION would have, at the end of the first twenty years of its publication, a regular supporting membership of over 15,000 Having furnished the foregoing facts, which will enable each reader to see clearly the past progress and present status of the JOURNAL, in relation to its influence on the ratio of increase of permanent membership, I shall defer the consideration of the second and third topics until the issue of another number

RAILROAD TRAINS FOR NEW ORLEANS —We direct the special attention of the readers of the JOURNAL in the Eastern or New England States, to the important notice of Dr W E Anthony, of Providence, R I, under the head of Domestic Correspondence, on page 279 of the present number of the JOURNAL Those who desire to attend the coming meeting of the American Medical Association in New Orleans must acknowledge that the railroad companies are disposed to treat them with marked liberality, and it should insure a very large attendance

CENTRAL FREE DISPENSARY OF WEST CHICAGO — In the JOURNAL for January 31, 1885, we made some comments on the instability of medical institutions and interests under municipal or political control They related to the action of tne County Commissioners of Cook County concerning appointments on the medical and surgical staff of the County Hospital, and the appropriation of county funds in aid of free dispensaries for the sick poor

The Central Free Dispensary of West Chicago has occupied rooms in the Rush Medical College building for several years, and has received an appropriation by the Board of County Commissioners, annually, on account of the services of the Dispensary to the poor of the city and county During the last two years the College of Physicians and Surgeons, located in the same neighborhood, has also opened a free dispensary for the poor, and at a recent meeting of the County Board it was decided to change their annual appropriation from the Central Free Dispensary to that connected with the last-named college In alluding to this in our previous comments, we carelessly adopted the language of the newspaper reporters, and stated that the Board of County Commissioners had voted to move the Central Free Dispensary from the Rush Medical College building to that of the College of Physicians and Surgeons, when we should have said that the Board had voted to change their *annual appropriation* from one dispensary to the other The difference is an important one, inasmuch as the Central Free Dispensary is, and has been for several years, an independently incorporated institution, having some means for its charitable work besides the county appropriation, and is in no respect under the control of the County Commissioners, except in so far as relates to the reception of money from the county treasury It will continue to occupy its rooms in the Rush Medical College, and carry on its dispensary work as heretofore

STATE MEDICINE

SANITARY NEEDS

REMOVAL OF THE CAUSES WHICH CONTRIBUTE TO EPIDEMICS

A COMPETENT AND THOROUGHLY EFFICIENT BOARD OF HEALTH NEEDED

Address of DR W W JONES Before the Social Science Association, of Toledo Ohio

GENTLEMEN Since you have invited me to say a few words upon "the sanitary needs of Toledo, in view of the probable approach of cholera," I may commence by saying that the "needs" within our control are such as will promote health and prevent disease under any and all circumstances, with perhaps the addition of some quarantine agencies on its near approach, and more rigid sanitary inspection of emigrants and freight connected with them, also for refuge stations where cases of cholera break out among them while in transit, so that they can be isolated from the healthy

Prevention of Disease —It is the modest pretense of sanitation that it prevents disease and mortality, hence its effects are not seen except in the good health of a people and the low rate of mortality, which does not attract attention, and comes to be looked upon as the normal condition of the municipality The causes of disease, for the most part, which it is the province of sanitation to prevent, are so obscure as to elude the vigilance of the wisest detective, and net the conditions which favor malignancy, and promote its spread when its invasion has occurred, are very generally believed to be known

These causes pertain to the individuality of the person, his idiosyncrasies, temperament, constitution, and his surroundings

The first part of this proposition requires the study and discrimination of the physician to learn his particular tendencies to disease The latter, those influences which are without, and surrounding him, and from which he cannot to a certain extent escape

It is these influences from without which make it necessary to organize a Sanitary Board and clothe its officers with extraordinary powers, in order that one careless or ignorant person may not be the means of bringing disease and death upon his innocent family or neighbors Anyone attempting to answer the question of Toledo's needs, in anticipation of any epidemic disease, would inquire, first of all Have we a sanitary organization which is entrusted with the power, and is equal to such an emergency, knowing that its success largely depends upon the knowledge, skill and fidelity of such a municipal organization

In our city we call this a Board of Health, created by a statute of the state, clothed with extraordinary powers—legislative, executive, judicial and ministerial The complex functions bestowed upon this board require for their intelligent fulfillment the highest intellectual powers and attainments, coupled with a knowledge of what is known in very many of the sciences as applied to sanitation, as well as legal discrimination enough to avoid trespassing upon the just rights of others

The necessity for such a board in cities is of somewhat recent origin, and is the outgrowth of progress in the human mind in its attempt to stay the mortality of epidemic disease

Contributing Causes —It is a well settled fact that whatever conduces to disease in any form will increase the virulence of an epidemic which may prevail for the time being In this city cases of sporadic cholera are seen every year, and nearly all such cases are recognized by physicians as one of the forms of intermittent fever or ague So in an epidemic of the same disease (cholera) many of the cases commence as an attack of that disease

Some of the causes which produce disease in summer are heat, and extreme oscillations from heat to cold, impure water supply, poor or defective food, overcrowded and poorly ventilated apartments, animal and vegetable filth, defective drainage, and escape of noxious gases which contaminate the atmosphere Some of these causes require, for their inspection and finding out, a class of men with more knowledge and fidelity than is usually found in the ordinary sanitary policemen and inspector While a man may be a very good policeman to watch over your property and protect your person, he may be so ill qualified to observe causes of disease as to tread over them without notice

In ordinary times when health is the normal condition and disease the exception, a street commissioner may perform the duty of health officer and sanitary inspector, and the functions of a Board of Health may be exercised by persons elected for other duties without exciting any just comment

But when an epidemic like cholera invades a community, there comes a frenzied demand for that kind of help upon which reliance can be placed, that all will be done which skill and knowledge can accomplish

Our whole sewerage system needs to be inspected and its defects remedied Many years ago it was discovered that the catchbasins leading into the sewers of the lower part of the city *had their traps originally built wrong side up*, and I have heard complaints every year since of their offensiveness by residents and people who have been compelled to pass them We all know that sewer gases may breed the worst pestilential diseases, and that, when once set up in a family, may spread to widely separate parts of a city, through infection transported by friends and acquaintances, and cannot be easily stamped out except by the strong force which is by law reposed in a board of health

My observation and experience with cholera in this country has convinced me that it is not contagious, as that term is used in connection with small-pox, measles, mumps, and, perhaps, whooping-cough in children, but that its spread is greatly due to that undefined and undetermined influence of mind upon mind, which is more felt than seen, and which disturbs the individual by its depressant action upon his mental and nerve force

Many years ago, during our cholera epidemics, I used to see illustrations of this in the Irish emigrants whom I used to be called to attend, who, when asked what was the matter, used to reply, "Och, Doctor, I am sick at the heart"

Though this was a somewhat apt illustration of homesickness, yet when pushed a little further, coupled with the fear of some invisible foe who is to be escaped from, it becomes a panic The history of our country is full of instances where panics caused by the prevalence of epidemic disease have blasted the prospects of towns and cities for whole generations

Say what you will of miasma, of germs and other influences which are the potent factors in causing ordinary disease, they exercise less influence in the production and spread of cholera than those just alluded to as affecting nerve force Every surgeon in the late war knows that it was the scourge of the army Every physician of extensive observation has seen its blighting effects, and will concur in the statement that it is the first thing to be watched for at the bedside, and its failure most to be dreaded

People repose confidence in an army in proportion to the perfection of its organization and the firmness, intelligence and experience of its commanding officers So will a people have confidence in a board of health in proportion as it is made up of those best qualified to grapple with the intricate problems of sanitation

Cholera in 1849 —In 1849, when the cholera epidemic first appeared in this city (for we were scarcely a hamlet in 1832 and 1834 on its previous advent in the country), the common council organized a sanitary force consisting of a board of health, aided by three or four of our best citizens in each precinct of the city, whose duty it was to call to their aid such nursing and medical skill as they required for the benefit of any who needed it, and also act as a committee for house to house visitation A crown of laurel should ornament the brows of those men if living, and the highest honors be paid to their memory if dead, for they carried us safely over the pestilence, without as much as a stampede of persons or business The grass never grew in our paved or other streets, as in a sister city from a human panic, and we are now enjoying the reward which accrued from the courage and fearless exposure of those men who battled the scourge of 1849 in this city

Epidemic Panics —The more ignorant, superstitious and poor the population of a city, the more liable it is to become panicky and suffer from an epidemic An illustration of this happened on the east side of the river in the year 1854 That suburb of Toledo was not at that time attached to the city, and contained only about one hundred and fifty people Cholera had been prevailing in the city since May 5 (the first cases having been brought from Galena on the Mississippi river), when suddenly, about the evening of July 4 or 5, cholera broke out in that hamlet, and in twenty-four hours every house, with a very few exceptions, was deserted Over twenty deaths had occurred during that time, and as I traversed its streets in the evening, twenty-four hours after its advent, I counted a dozen coffins filled with victims abandoned upon the sidewalk

Scarcely a light to be seen in the houses, they had been abandoned, and their occupants had fled to the farms in the rear, and the towns up the river, where the tales they told and the panics they created caused the death of hundreds of people The picturesque and thrifty town of Perrysburg lost many of its most prominent citizens Early in the course of the epidemic, Dr Robinson, one of the best physicians of that town, sent for me, and when I reached his bedside about eleven o'clock in the evening, he was dying I can never forget the words he addressed me, "Doctor, I have said much about the want of skill of you doctors of Toledo, because you fail to cure cholera, and let so many people die when there was no need of it I wish now to say that I take it all back I have seen and treated it, and my patients have all died I am dying myself from it, and have no wish to live longer, you can do me no good, the town is full of cases of that disease, go with Dr Peck, and see if you can do them any good" I worked the balance of the night among the terror-stricken inhabitants, making house to house visitations with Dr Peck, and returned to the bedside of my medical friend at the dawn of day, but his eyes had meantime been closed in death

First Case of Cholera in 1854 —The following extracts, from my clinical note-book, of the first case of cholera occurring here in 1854, illustrate the depressing influence generally found accompanying cases of cholera

Miss ——, aged 20 Arrived in this city on the afternoon of May 3, 1854, in company with an uncle, Wm H Hall, Esq , an attorney of this city, from Galena, Ill Had been where cholera prevailed on the Mississippi river, and a lady had died of it at a hotel in Galena, where they had stopped She told me that she had been considerably alarmed on the way here, and was afraid she would have it, and it had greatly worried and prostrated her

"I first saw her at 9 A M , May 4 She had no perceptible pulse at the wrist, extremities, tongue and skin cold, voice husky, fingers and lips blue, had had watery discharges every few minutes since 2 A M , with occasional vomiting and cramps in the muscles of the extremities, died at 12 30 M

What a Board of Health should be —In the organization of a board of health, it is not necessary or desirable that it should be made up exclusively of physicians or sanitarians An attorney who can guide the board amid the pitfalls of legal opposition, an engineer who understands the best means of overcoming those physical causes which promote and spread disease, and the sagacious property owner whose pecuniary interest prompts him to act for the best interest of himself and others like him, are as indispensable as the most accomplished sanitarian All the members of this board should be imbued with that zeal for the cause of humanity which belongs to the just and fearless, and having this accomplishment, petty or partisan schemes will find no favor in its councils, and no fears need be entertained that its individual members will not soon acquire (if they had it not before) the sanitary knowledge which will enable them to accomplish the expectations in their appointment

The sanitary needs of Toledo, as well as every other city, whether in times of health or sickness, prosperity or adversity, is "a live Board of Health," such as the statutes of the state contemplate The original forms for their appointment by our municipal code have been changed from time to time to suit the changing phases presented in the life of the different municipalities, their exigencies and their needs, and the views of legislators for the time being These changes have principally related to the appointment of members of such boards In some cities these appointments are made by the council, in others elected by the people In our own, its functions are exercised by a police board All of these modes of appointment at one time or another have been found to be so objectionable as to invite change

How constituted My own opinion is, that the nearer you can get the appointing power to individual responsibility, the nearer perfection such an organization will approach If asked my plan, I would say, put the appointing power in the mayor or presiding resident judge of your common pleas court, whose reputation would be at stake in appointing fit advisors in life and health Such a plan may at first strike one as being objectionable While I admit that it may occasionally prove so, yet all other plans so far tried in this state have been found wanting in one municipality or the other, and sometimes, in attempting to better them, have made them worse A knowledge and history of the sanitary legislation of the state shows that some has had its birth in supposed partisan necessities, much in needed reform, and more in a desire to improve the physical and organic welfare of the people Some of its wisest and most efficient provisions for preserving the health of the people of the state (and which I have never noticed in the laws of other states) have emanated from sanitaries of this city, and yet we have never had a special sanitary club to aid, or spur each other on in the business of preserving and propagating the knowledge of how to preserve health, which the most obtuse must admit is worthy of the highest aims to which the individual can aspire A knowledge of this science, the most important for the happiness and moral good of the race, is not even taught, in its elements, in the public schools A moiety of this knowledge would deliver our people from the imposture practiced upon them by the innumerable horde of quacks who infest our city and state only to sponge out the lifeblood from a confiding people

"Life is short and art is long"

Apply the latter to sanitary science, and some appreciation of the magnitude of the subject may be perceived The ever changing phases of human life in the individual, in the community and in the nation, from its infancy to maturity and decline, the subtle influences which produce disease, blast the hopes and bring sorrow and pain such as makes life a burden unto very many of our race, agencies which affect innocent children, mature age and embitter the decline of life, are all comprised in a knowledge of sanitary science

Only the first steps in the long ladder to the goal for which boards of health are organized can be trod in one generation, and one may reasonably fear that a glimpse within the veil where the day is all sunshine will never be permitted to mortal eyes

Few men can appreciate the benefits to be derived from an efficient sanitary organization in both city and country, and yet all men ought to realize it when medical bills are presented

This city furnishes support to more than one hundred physicians and their families, when they have any It is safe to say that their least average cost to the people per annum is $1,000, making an outlay of $10,000 for medical services, besides supporting forty retail drug stores, not to speak of the hosts of traveling and other quacks whose advertisements crowd the newspaper columns and billboards to the detriment of respectable reading matter

Seeing the indifference which exists even among our most intelligent people in regard to life and health, there is great danger that philanthropists and sanitarians will lose heart and give up the self-imposed task of urging measures which are of the most vital consequence, not only to this, but of unborn generations

Many years ago a duty was imposed upon me by the Ohio State Medical Society, of visiting and urging upon the general assembly of the state the propriety of establishing a state board of health While the members of the Legislature heard me patiently and seemed to acquiesce in my views, I found, upon sending detectives to ascertain what they really thought about it, that their answer was, "That fellow wants an office "

Satiated with disgust at the obtuseness of these legislators, and thoroughly convinced that to be one of them, even if I could, would be degrading by mere association, I resolved to return to my own city and spend what influence I possessed among a people who could appreciate honest effort for its own sake, and whose estimation of the benefits of sanitation was not limited by the desire to promote this or that man to a political office

Thanking you, gentlemen of the club, for the courtesy you have extended in asking me to address you, allow me to express the hope that a new interest may be awakened in the city that shall result in lasting benefit "

At the conclusion of the paper, a lengthy discussion was entered upon, participated in by a number of medical gentlemen and others The sentiment was substantially universal that what is needed is a health board composed of men in whom the people will have confidence—that such confidence is the best possible protection against a cholera epidemic—and finally a motion was unanimously adopted appointing Dr W W Jones, Hon Guido Marks, Wm Baker, Esq , and Hon Richard Mott, a committee to prepare a bill for presentation to the legislature providing for a board of health independent of the police board

The association thanked Mr Jones for his able address, and it was announced that at the next meeting Wm Baker, Esq , will read a paper on "The Benefits Arising from City Parks "

FOREIGN CORRESPONDENCE.

BERLIN LETTER.

Berlin, Feb 10, 1885

Medical Notes—Syphilis — Pneumonia — Typhoid Fever —The late lesions of syphilis are treated here with full doses of potassium iodide, from ʒss to ʒij at a dose Such an amount as this must be given in *full* dilution and preferably after eating There must of course be always more or less danger of iodism, of fatal swelling and irritation of the mucous membrane, and at Prof Fraenkel's clinic, not very long ago, a man presented himself with œdema of the glottis brought about by such heroic treatment Its toleran ce depends very much upon the idiosyncrasy of the patient, and also, I think, upon the extent of the disease I have seen it written somewhere that the ability to bear such doses without inconvenience was a sure indication of general infection, and from a somewhat extended observation of many hundreds of cases in Berlin, I am inclined to believe that this is a fact Only exceptionally have I noticed any derangement of the stomach following even the largest doses, when such were given in full solution One hundred and twenty drops of a saturated solution in a goblet of water will rarely distress the individual Gummata of the tongue, intractable syphilides and syphilitic paralyses yield more surely to these large doses than to any other plan of treatment I know of one case healed experimentally with chlorate of potash pushed to its physiological effects, and whether *post hoc* or *propter hoc*, I know not, but the patient certainly improved rapidly and surely Small doses of potassium iodide, say two drops of a saturated solution well diluted, and taken *very* slowly, is one of the best things I know of for congestive headache In the earlier stages mercuric bichloride given hypodermically is much used in Dr Lassar's polyclinik, together with massage Pneumonia is severely let alone so far as medicines go Nature is not handicapped with nostrums, and is supplemented by the physician's art only when her own powers become weakened by watching Careful nursing, judicious and ample feeding and proper ventilation are insisted upon Careful nursing means a constant surveillance over the movements of the patient, so that he may not improperly expose himself, the administration of food and alcohol (when demanded) at certain regular hours, and an hourly observation of pulse and temperature, so that the attending physician may be notified of the least alarming change Starvation diet does not obtain many friends Fevers eat and consume tissues, and the waste must be compensated for by full feeding not over-feeding or improper feeding, which may set up gastric disturbances, but just such as the system requires The intervals between feeding should not be too long, and the restless patient will require quite as much during the night as during the day Pulmonary inflammations are recognized as due to causes quite different from those which until lately possessed the German medical mind, and with these new views of pathology and etiology have come new ideas of treatment, or rather a belief in no treatment at all, and a reliance upon hygienic detail and nursing The disease has a tendency to cure itself, if the patient be placed in the best possible condition for nature to assert her powers This is also true of typhoid fever An expectant plan is very generally pursued The alkaloid *antipyrin* (dimethyl-oxychinin), first introduced by Prof Filehne, of Erlangen, was quite the rage for a time, but interest in it is fast dying out, and clinical experiences do not sustain the hopes that were based upon physiological experimentation At best, fever is but a symptom of a general condition, and it advances or retrogrades just as the primary cause becomes better or grows worse The cold pack works admirably over here in excessively high temperatures, and the patients always seem to feel better after it has been used The iodine treatment has also shown itself to be of little reputation In those conditions in which the high temperature may be due to irritability of the nervous centres, the pack soothes and controls, and is not followed by any of the distressing symptoms which sometimes attend the administration of quinine, antipyrin, etc Ulceration of Peyer's patches is guarded against by *absolute* rest by non-irritating food, and by careful attention to the bowels Claret is given in full quantities, also other kinds of wine, milk, and good bouillon Medicines are only given when certain well-defined symptoms seem to demand them The matter of *rest* is a most valuable consideration in the treatment of any disease, and the surgeon would be less frequently called upon to operate, the physician to prescribe, or the specialist to theorize if it were possible to carry out such a regimen in all of its details in every instance *Rest, air* and *food* supply the normal demands of a normal body Every day the science of medicine is emancipating itself from traditional fetters and superstitious vagaries A walk through the wards of Charite would fill the old-fashioned practitioner with grief, and he would have a poor opinion of Berlin as a medical centre Real's treatment of typhoid fever by full doses of bismuth subnitrate is not a success Koch's views as to the causation of acute miliary tuberculosis and chronic phthisis are now receiving considerable attention, especially from Drs Biedert and Siegel Koch, you remember, advanced the theory that when small numbers of the bacilli entered the lungs repeatedly, chronic phthisis resulted, but when a large number suddenly entered the lungs we had a miliary tuberculosis This theory, highly ingenious though it may be, cannot stand alone, it needs a long line of corroborative proof and parallel investigation What coincidence limits the number and governs the entrance of the bacilli into the lungs? What is the peculiar idiosyncracy which makes the disease so rapidly fatal in some people? Why is it that some will escape infection even when the conditions for the entrance of the bacilli into the lungs are those most favorable? Biedert and Siegel maintain that phthisis is not an infectious nor a contagious disease, and that the lungs must be already diseased before the bacilli can produce the characteristic changes In a perfectly healthy organism it is questionable whether the bacilli can produce such changes Biedert and Siegel's investigations are elaborate and far-reaching, the abundance of material at their disposal gave them every opportunity to vary their researches, and their conclusions will be read with interest Of course, the bacillus, when found in the *sputum*, is *absolutely* pathognomonic Such microscopical examinations are made every day in Fraenkel's, French's and Senator's clinics and in the offices of private practitioners But the shape of the bacillus is *not* always the same, neither is the relation of the amount of bacilli to the lung affection as yet thoroughly understood The theory that consumption depends upon the presence of bacilli *only*, cannot stand without a very much larger burden of proof than we yet possess At present it seems to be held by medical authorities that heredity and extraneous influences impress certain conditions favorable to infection upon the lungs Dr Anfrecht, of Magdeburg, believes in the identity of croup and diphtheria, and thinks that local applications are injurious He uses simple cold compresses and a gargle of chlorate of potassa

PARIS LETTER.

PARIS, Feb 13, 1885

At a recent clinical lecture at the Hotel Dieu, Prof Germain Seé thought proper to expatiate on the diagnosis, or rather the characteristic appearances of the eruptions of the various eruptive fevers, as he found that at the examinations for the doctorate, the candidates generally manifested an unpardonable amount of ignorance on the subject Prof Seé pointed out the necessity for using the clinical thermometer in such cases, as indeed in all caases of fever, and rendered justice to Wunderlich for his admirable researches on thermometry, which have singularly facilitated the diagnosis of various maladies which would otherwise have been enveloped in obscurity For instance, apropos of eruptive fevers, the study of the temperature of the body during an attack of fever would be indispensable, as before the appearance of an eruption the exanthematous fevers do not present any pathognomonic sign, and it is here that the thermometer would be of great service to the physician, as even after the appearance of the eruption it is sometimes difficult to differentiate these fevers one from the other It must, however, be borne in mind that the elevation of the body temperature is not altogether proportional to the intensity of the eruption; in other words, the study of the *temperature would be of value only by the course of* the latter, and not by its maximum. For example, in small-pox the initial temperature rises promptly from 98.6° F. to 102.2° F., and on the second day in the evening, or forty-eight hours after, when once the eruption appears, the defervescence is complete, and the *variolous eruption follows its course without* the thermometer indicating an increase of heat. The thermometer, however, rises again at the stage of suppuration.

Scarlatina begins much in the same way as variola; that is, brusquely; but the body temperature rises much more rapidly, and reaches its maximum in twenty-four hours, and it is then that the eruption appears. But it often happens that the scarlatina passes unperceived—either that the eruption is so pale that it escapes notice, or it may be completely absent (scarlatine fruste of Trousseau); or, finally, it may be very incomplete or fugitive; and yet these sorts of scarlatina may give rise to the accidents observed in regular scarlatina; such, for instance, as Bright's disease, albuminuria, and children will be the more exposed to these complications, as under the above circumstances the necessary precautions would be neglected. This error may be avoided if care be taken to attend to the body temperature. At the commencement it may be that there is fever; it is of short duration, lasting twenty-four hours, but the thermometer reaches, in this lapse of time, 104°F., and no other malady but scarlatina attains this maximum in one day. In any case, Professor Seé would recommend that no patient suffering from scarlatina should be allowed to go out of doors before the twenty-fifth day, *for* statistics have shown that, nine times out of ten, it is between the twelfth and the twenty-third day that scarlatinous nephrites are declared. It must be borne in mind that in scarlet fever the thermometer remains at its maximum during four or five days, and that the defervescence takes place about the seventh *or* eighth day; the decline is slow.

Measles commences slowly and insidiously; its course is therefore essentially different from that of scarlatina and variola. Whilst in variola the temperature attains its maximum rapidly and in a continuous manner, in measles there are remissions in the morning, so that during the first two days the physician may be led to believe that he has to do with typhoid fever, but the doubt is dissipated the third day, or when the thermometer marks over 102.2° F., as the body temperature in measles rarely goes beyond this figure. The following is, then, what may be observed in measles. At the commencement there is little fever, but it is not continued; it has the character of remittent or catarrhal fever; then comes on a transitory attack, preceded by shiverings, about the third day; the thermometer falls in the morning from the fifth to the sixth day, and then the eruption appears at the end of this or during the following day. The maximum of the temperature may therefore be noticed from the third to the fifth day, and the defervescence from the seventh to the eighth day. The relative differences between the eruptions are as follows. In scarlet fever, when once the eruption *appears, the thermometer rises or remains stationary.* In small-pox, after the appearance of the eruption, the thermometer falls rapidly, to rise again on the eighth day, if there is any suppuration. In measles, after the eruption, the thermometer rises again one day, then falls, but slowly.

DOMESTIC CORRESPONDENCE.

CINCINNATI LETTER.

The unparalleled good health which blessed our city and cursed our physicians for 20 months following the great flood of Feb. '83 was broken last October by an epidemic of measles. In January '84 there were 5 cases of measles *reported* in the city. February 2, March 3, April 4, May 6, June 13, July 10, August 6, September 6, October 104, November 323, December 355; Total 837. Of deaths there were none till July, when one was recorded, August 1, September 1, October 12, November 23, December 31; total 69—one in 12.13 of the cases reported died. The registrar of vital statistics, however, is authority for the statement that only one case in 3 is reported. Many physicians neglect to report them, although such neglect is finable. Many children are treated by home remedies, or a physician being called for the first child sick in the family, those subsequently ill are treated with the same remedies which cured the first. On the contrary, there were reported 250 deaths during the year, measles having occurred 2 or 3 weeks before the death. As to the history of the spread of the epidemic throughout the city. In January, 1884, it was found in the eleventh ward, starting at a schoolhouse. In March it extended to the seventh ward, immediately south. In April into the thirteenth, west of the eleventh. In June in the twelfth, north of the thirteenth and west of the eleventh. In July it appeared in the tenth, south of the thirteenth and west of the seventh. September found it in the third, east of the eleventh and seventh. In October it appeared with great virulence in the twenty-first ward, in the extreme western part of the city, apart from the wards previously implicated. In November and December it was found in all parts of the city. The river wards, known as the flooded district, escaped with comparatively few cases. The great bulk of the cases were in the region known as "Over the Rhine," inhabited by Germans, and the most thickly populated part of the city. Since the first of the year the epidemic has decreased very rapidly. The epidemic was considered to be of so much importance that it was given two meetings at the Academy of Medicine.

The first meeting was given up to the discussion of the subject opened by Dr. J. C. Cleveland. Dr. Forcheimer reported a severe epidemic which visited the children's hospital. A child was brought in supposed to be suffering with cerebro-spinal fever, which afterward developed into a fine case of measles Seventeen cases followed, nine of which proved fatal The enormous fatality was due, he thought, to the bad condition of the patients at the time of the attack All of them were confined to the bed with various diseases of more or less gravity One of them was brought to the hospital in a moribund condition Dr Haarf at the next meeting reported "measles and scarlet fever occurring simultaneously in his own family" His five children contracted measles, and three of them had scarlet fever also, one having had scarlet fever before The interesting part of it is that his wife, who was pregnant at the time, gave birth to a child in an adjoining room to the children, both being heated by the same stove and she being attended by the husband and father, who also attended the children After all this courting of trouble, as it were, the wife and mother made a good recovery

One of the remedies used was the hydrochinon, of which the doctor and also the president, Dr Wenning, spoke very highly They praised it for its absence of taste, its ready solubility in water, its diaphoretic and antipyretic effect The epidemic of measles just closing has been remarkable for its complications, pneumonia, broncho pneumonia, bronchitis, entero colitis and ophthalmia were those generally noted

Dr G A Fackler, the Secretary of the Academy of Medicine, reported at the last meeting an interesting case of meningocele occurring in a child whose mother during pregnancy was subject to attacks of hysteria

Dr E S McKee, at a recent meeting of the Academy, reported a case of "repeated miscarriage successfully treated with chlorate of potassium" The patient had ten successive miscarriages in sixteen years of married life, from two different husbands, occurring from the fifth to the eighth month, no single child coming to term In the eleventh and twelfth pregnancies she was put on chlorate of potash, from fifteen to thirty grain doses, and both children were brought to term and delivered healthy One died in infancy, the other still lives This paper was extensively discussed

In the year just past, there were 6,609 deaths in the city, 5,667 were residents, 538 were non-residents, 404 were still births Births recorded, 8,363, marriages, 1,814

There were 10,646 patients treated by the district physicians during the last year These received 15,795 prescriptions, at a cost of $4,733, average cost of prescription 31¼ cents Births recorded, 8,363

A case of rodent ulcer of the face occurred recently at St Mary's Hospital under the care of Dr J C McMechan It occupied the whole side of the face, implicating the orbit and the greater part of the nose It reached within two lines of the inner canthur of the only remaining eye The doctor cauterized the wound, and especially the cutaneous edges, with the galvano cautery Since this there has been no advance of the disease and the patient is doing well

Of cocaine we do not hear so much now as before the holidays Then we heard of little else from our ten ophthalmologists

Our medical colleges are not so well patronized now as formerly The decrease this year has been fully 30 per cent This is laid at the doors of politics, hard times and overproduction A week from now both our colleges will have had their commencements The class in the Ohio will probably number seventy, in the Miami about thirty, that is unless there is a larger per cent of refusals than usual A medical school in a neighboring city, which has a so-called summer session, has sent out its regular annual bid asking the students who do not pass here to come there and take their diploma One who failed to pass here last year, being unable to tell the professor of anatomy how many teeth or how many ribs he, the student, had, went to our neighboring city, took his diploma in June, came back here and settled The spring courses in the colleges here will commence March 15 and continue to the end of April They are conducted exclusively by the adjunct faculties, and are on the recitative and practical order Clinical lectures are conducted in the Good Samaritan and Cincinnati hospitals

There is rumor upon rumor that we are to have a new weekly medical journal The child has been christened "*The Argus*," and an editorial father found for it, Dr J M French, but the delivery is tedious If born, 'tis to be hoped that it will be more vigorous than some of its class we now have

There is rumor upon rumor that we are to have a new medical journal The child has been christened "The *Argus*," and an editorial father found for it, D J M French, but the delivery is tedious If born, it is to be hoped that it will be more vigorous than some of its class we now have

---

NEW YORK LETTER.

NEW YORK, Feb 27, 1885

A scientific meeting of the Fifth, or Southern District Branch of the New York State Medical Association, was held in Brooklyn, on the 25th of February It was the first meeting of one of the five subdivisions into which the parent association was organized at the annual meeting in November last, and it was an exceedingly successful and pleasant gathering In his brief opening address the President, Dr J C Hutchinson, of Brooklyn, said that the desire of the friends of medicine represented in it was ultimately to arrange for frequent meetings in Kings and other counties of the district Having alluded to the remarkable process of the state association, which was joined by more than 500 members during the first year of its existence, he went on to say that mere numbers was not the object The aim was to get the best material for effective and congenial work on behalf of the best interests of the profession and of the public One of the great features was freedom from legal control, or complications The association wanted nothing to do with the legislature, or any other political body It desired to be free to admit or reject whom it pleased

At all times ready to give information, when requested, to the civil authorities, executive, legislative or judicial, it still wished no official connection with them, for medicine was a voluntary, self-independent profession, governed by its own rules At the same time, toward all our brethren of a like faith, but of a different policy, all the Fellows of the association, he knew, would have only the kindest feeling Men of culture and honor could differ without anger or loss of mutual self-respect He was persuaded, he said, in conclusion, that as the branch association completed its work of organization and engaged in the professional objects and dealt with the subjects germain to the healing art, their union would be found pleasant and profitable, and one crowned with the approbation of their consciences and with beneficial results to humanity, to science and to themselves

The first scientific paper was an elaborate one by Dr J W S Gouley, of New York, on "Contracture of the Bladder, Consequent on Cystitis" In giving an account of the exciting causes of cystitis and contracture, he stated that ordinary polyuria from nervous influences, when maintained for any length of time, was likely to produce these affections equally with conditions of the urine in which the specific gravity was very high, as in diabetes The explanation was, that when the urine was of low specific gravity, the epithelial cells of the mucous membrane of the bladder, by an endosmotic process, became swollen and then died and were cast away, while, when it was of high specific gravity, the epithelial cells, by an exosmotic process, shriveled, died and were cast away The final result being the same in either case, the denuded mucous membrane suffered constant irritation from the urine in contact with it In vesical trouble from enlarged prostate, he claimed that there was universally hypertrophy of the bladder, instead of atrophy and atony, as stated by many authorities, and that although he had witnessed a very large number of autopsies, he had yet to see the first case in which there was atrophy

One of the causes which he mentioned was the use of ether as an anæsthetic, and he said he wished to allude to this as a warning to surgeons In thirty cases out of one hundred operated upon for hemorrhoids, he had found that there was contracture of the bladder, originating in the effect caused by the ether inhaled at the time of operation The action of this agent was twofold—first, upon the kidneys, producing polyuria and, second, on the urine, which it rendered irritable in character There was apt to be retention of urine from tonic spasm of the neck of the bladder, and hypertrophy with chronic contracture finally resulted In order to avoid these unpleasant consequences, he advised that a patient about to undergo an operation should always be required to evacuate the bladder immediately upon taking ether, and again, also, as soon as he recovered sufficiently from the influence of the anæsthetic

Dr Austin Flint made some extended remarks on an interesting case of aneurism of the arch of the aorta, in which the difficulties of diagnosis were unusually great, and also presented the specimens from the same When he saw the patient, in consultation with two Brooklyn physicians, he found some difficulty of respiration, but this was not very great at ordinary times There was, however, distinct stridor, though careful laryngoscopic examination had failed to detect any abnormal appearance in the air-passages When an examination of the chest was made, it was found that the respiratory murmur was notably feeble on both sides, and that it was a little weaker on the left than on the right This was all that could be detected at that time, but before he had left the house he was summoned to see the patient, who was suffering from a paroxysm of the most intense dyspnœa This was more marked in inspiration than in expiration, and was so aggravated in character that it seemed that he must expire at any moment In about half an hour, however, he had recovered from it, though within thirty-six hours afterward he really did die in a similar paroxysm During these paroxysms, to which the patient had been subject for some time, the radial pulse and that of the carotid artery on the left side were found to disappear altogether

In considering the morbid appearances found after death in connection with the symptoms observed during life, Dr Flint showed that the ascending, transverse and descending portions of the arch of the aorta were all very much enlarged, while there was marked atheroma of the part present Under the circumstances he thought it quite remarkable that a loud, bellows-like murmur had not been caused For the absence of the left radial and carotid pulse during the paroxysms, the unusual distension of the aorta and the consequent pressure on the left subclavian and carotid arteries were sufficient to account In addition to the general enlargement, there was a pocket, about half an inch in diameter, which protruded directly into the trachea, and which must have caused, of course, more or less obstruction to respiration It was evident that, if life had been prolonged, the aneurism would have made its way into the trachea and eventually ruptured with fatal result

Dr Flint thought that there could be no question that the paroxysms from which the patient suffered were due to the effect of pressure on the recurrent laryngeal nerve, but it was an interesting question whether the urgent dyspnœa noticed was the result of paralysis of the nerve or of spasm of the glottis It was more rational to suppose, he said, that pressure on this nerve would give rise to paralysis rather than spasm A question of interest in connection with paralysis of the abductor muscles of the glottis, which he believed to be the real source of trouble, was, Is such a paralysis on one side sufficient to cause death? It seemed to him probable that it was not, but when one side was affected there was a strong liability, through some sort of sympathetic or reflex action, the exact nature of which was not understood, of the paralysis becoming bilateral

The last paper, on Oleate of Cocaine, was read by Dr E R Squibb, of Brooklyn The results of the application of the aqueous solution of cocaine to the skin for the purpose of producing local anæsthesia had, he said, proved very unfavorable. The chief difficulty in its application had appeared to be the difference between the epithelium of mucous membrane and the epidermis, and the impermeability of the latter. There was no possibility of finding a liquid which would pass the epidermis with the same facility as the watery solution passed the epithelium; but it had occurred to him that if a preparation could be made which would pass one-seventh as fast, and if it were made seven times as strong, the conditions would seem to be met for making as successful applications of cocaine to the skin as to the mucous membrane, with the exception that more time would be required, of course, in order to secure the action of the drug. He then gave an account of the various steps by which he had arrived at what he believed to be the most available preparation for use, viz. one containing 25 per cent. of cocaine, in an excess of oleic acid, a strength just about seven times as great as that of the ordinary 4 per cent. aqueous solution sold in the shops; after which he narrated a considerable number of experiments which he had performed for the purpose of testing the anæsthetic power of the oleate when applied to the skin. He stated that the conclusion thus reached was, that the hope which had been entertained that cocaine employed in this way might prove a useful anæsthetic, had been completely disappointed. Except for certain special applications, as, for instance, to the glans penis, anus, etc., and possibly for the relief of trigerminal neuralgia, in which it had not yet been tried, the oleate of cocaine had to be pronounced a useless preparation.

After the scientific proceedings, a very interesting portion of which was the discussion which followed each of the papers, a bountiful collation was spread in an adjoining room. P. B. P.

TREATMENT OF THE INSANE.

EDITOR JOURNAL AMERICAN MEDICAL ASSOCIATION.

Dear Sir:—The question of the proper treatment of the insane is one which has been ably discussed by specialists and others supposed to be particularly familiar with the subject, and should, therefore, be warily spoken of by the non-expert. But there are some things which common sense teaches where (alleged) science is dumb. Some of these things are likely to strike one with particular emphasis upon his first visit to an institution for the care of insane. The realization of facts is peculiarly vivid, and one receives an impression of the condition of things which is, as yet, not deadened by constant contact. Perhaps such impressions are fanciful and born of sentimentalism; if so, the ever alert and practical boards of charities, etc., will see through their flimsiness and brush aside their sophistries, and they will melt quickly away before the blazing sun of science; if they are real, publicity is desirable. I had the unfortunate occasion recently to take to an asylum for the insane a young man suffering from mental derangement, though quite sufficiently intelligent to understand the cause of his condition, the necessity for its alleviation, and to express a desire to go to the asylum for its treatment. Upon his arrival there he was placed in a ward with some forty or fifty others, none of whom were more intelligent than he, many of whom were much less so, and locked into their company to enjoy the benefits and felicity of their refining and elevating intercourse and conversation. Undoubtedly locks and bolts are necessary in the vast majority of cases, but discrimination is desirable even in insane hospitals. To one who goes there of his own will, and for an understood purpose, conscious of his mental defects and anxious for their relief, they are not only useless, but abhorrent, and tend to destroy what little self-respect and self reliance the weakened mind is capable of feeling. Whatever his other needs may be, a patient of this kind certainly *does not* need the influence of surrounding minds as deficient, or more deficient than is his own; and to be confined, virtually a prisoner, with his days and his nights a constant routine of alleged pleasures and certain contact with his mental kind, many be a scientific way for the treatment of some insane, but practically I apprehend it is a pitiable failure so far as results are concerned. I will only trouble you to speak of one more point, and that is, the fact that asylum managers should be men of large experience in the general treatment of disease. I hold that one, whatever his natural abilities, cannot graduate from college a full fledged specialist in the treatment of the insane. When we remember the study and research which has for years been devoted to this subject, its importance as a public charity, its relations to the unfortunate beings who made its existence necessary, it is nearly a mockery to find at the head of one of these institutions, containing 500 or 600 people, a man of small experience in years, absolutely none in the general practice of medicine, and, as I am credibly informed, only three or four years a graduate of a medical school. Comment would appear to be superfluous, but as the craze now is for specialism in medicine, this institution seems to afford its realization; is, indeed, its utopia.

I am, yours truly,
J. B. STAIR.

DETROIT, MICH., Feb. 17, 1885.

TO THE EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

In your issue of February 14, there is a review of the 2d edition of my "Manual of Bandaging," signed by "E. W. A." As this review contains statements that are far from the truth, I ask you for the liberty of replying.

The reviewer starts with the assertion that the book "is full of references to charpie, plumasseau, gateau, boulette, bourdonnet, cataplasma carbonis, and other strange and barbaric things which modern surgery has no use for."

In reply to this charge, permit me to say that on just *three*, no more, pages of the book, where their definitions and descriptions are given, do these terms occur; hence this statement of the reviewer is decidedly untruthful. Neither was I aware before that such pharmaceutical terms as "cataplasma carbonis," "charpie," etc , were "barbaric," since these terms are found in all our standard works upon pharmacy and surgery

Another misstatement is the following "The preface informs us that the work has been used in medical colleges, *but there must be some mistake about this*" (Italics mine) As the reviewer is so ready to assert that I was mistaken when I wrote this statement for my preface, I would refer you, to confirm *my* correctness, to the catalogues of the two Schools of Medicine at Ann Arbor, Mich It is not necessary to name others, as I might do, in order to show the incorrectness of *his* statement

As to the assertion "that a student who should make this manual his authority would be a veritable Rip Van Winkle," it can be best answered that the very day your *Journal* was received an order came *from a Chicago house for ten* of these "Rip Van Winkle" books, this being the *third* shipment of them to your booksellers this winter, also, just a short time previously, fifteen copies were ordered by the house surgeon of Mt Sinai Hospital, New York city, for their nurses, that one edition of the book has been sold, and that the second is now nearly exhausted

As to the fault found because I used scientific terms to name a bandage, I would say that *only* anatomical terms are made use of, and I do not hold myself responsible for the terms other generations have given the different portions of the human system I simply made use of these terms because I supposed the merest tyro of a medical student knew his anatomy sufficiently well to know what I meant when speaking of, for instance, the "occipito sternal triangle" To aid such as "E W A," who object to anatomical terms, I have always given the *common* name of the parts covered by the bandage when such has been possible, and rarely, I am free to say, has the common name been as plainly descriptive of the bandage as has the anatomical If one knew little or nothing of anatomy, then the common name, which "E W A" seems to prefer, would be the one to use

Your reviewer also states that I purloined or compiled my Manual from "one or two little works on bandaging which are still extant upon the shelves of older practitioners"

This is a grave charge, Mr Editor, and I pronounce it as absolutely false, and call upon "E W A" for the names of these "two little works"

Yours truly,

C Henri Leonard

Providence, R I, Feb 18, 1885

Editor Journal American Medical Association

Will you please notify the delegates to the American Medical Association from New England that arrangements have been made to run a special train from Boston to New Orleans for the accommodation of physicians and their families Leaving Boston on Friday, April 24, at 3 P M, Worcester at 4 20, Springfield at 6 15, arriving in New Orleans on Monday 27th, at 9 A M Returning, leave New Orleans Friday, March 1, about 6 P M The fare for the *round trip* will be from Boston, $41 50, Worcester, $40, Springfield, $38 50 Further particulars and tickets to be procured from Dr W E Anthony, Providence, R I

Respectfully yours,

W E Anthony, M D

NECROLOGY.

William Braithwaite, M D, the well-known English physician and surgeon, and the founder of *Braithwaite's Retrospect*, died recently at his home in Leeds, in his 78th year He commenced the practice of medicine in Leeds in 1830, and filled several posts of trust in the hospitals and infirmaries of that city The first number of his *Retrospect of Medicine* appeared in 1840, and has now reached the 90th volume It has been republished in America for several years, and is as widely-known and valued here as in England The publication will be continued under the direction of his son

MISCELLANEOUS

Micro organisms and the Germination of Plants —M Duclaux has recently sent a communication to the Académie des Sciences on "The Germination of Plants in Soil Freed from Micro-organisms" He chose for his experiments the Dutch pea and the haricot bean, the first of which has its cotyledon in the earth, the second on the surface The soil having been sterilized before the seed was sown, germination did not take place This soil was also covered with milk, but this was not altered Thus it seems that it is essential to germination that there be micro-organisms in the earth

Mr Pasteur thus also states that he has found, by experiment on animals, that food which is free from micro-organisms cannot be digested, as they are necessary to the process of digestion

---

The Massachusetts Emergency and Hygiene Association, says the Boston *Medical and Surgical Journal*, February 26, 1885, has prepared a course of five lectures on School Hygiene, to be delivered in the hall of the English High School in Boston They are "Heating and Ventilation," by F W Draper, M D, "The Use and Care of the Eyes, especially during School-years," by C H Williams, M D, "Epidemics and Disinfection," by G B Shattuck, M D, "Drainage," by Frank Wells, M D, and "The Relations of Our Public Schools to the Disorders of the Nervous System," by Charles F Folsom, M D

The Yellow Fever Microbe —The *Lancet* states that recent experiments made by Messrs Mozly and

Harrison have served to throw discredit on the conclusions of Dr Domingo Freire, of Rio Janeiro, who has been so loudly praised by the lay and medical press as the discoverer of the pathogenetic element of yellow fever, the *micrococcus xanthogenicus* According to these observers he has mistaken septicæmia in the lower animals for yellow fever, which confirms the observations of the Havana Yellow Fever Commission of the National Board of Health

"Babyhood" is the title of a new, large, double-column monthly of thirty-four octavo pages, well illustrated, full of good and practical reading matter, and devoted exclusively to the care of infants and young children, and to the general interests of the nursery It is under the editorial charge of Leroy M Yale, M D, and Marion Harland, of New York The subscription price is only $1 50 a year, and its office is 18 Spruce street It is essentially a family magazine

Fireproof Insane Asylums —The Boston *Medical and Surgical Journal*, of February 19, says Why should not Massachusetts, at least, have a law in her statute-books that no new building should be occupied as a dwelling-place for any of those in her care until a report had been made in writing to the Governor by a proper board of fire experts that it was fireproof and thoroughly provided with fire apparatus?

Cocaine Disks —Dr Joseph E Warren, of Boston, suggests that the most convenient form for using muriate of cocaine in ophthalmic practice is that of gelatine disks He has used these disks with much satisfaction Each one contains about half a drop of an 8 per cent solution (gr $^{1}/_{5}$) This is a more economical method of applying the drug than that of using a solution

The Turin Prize —The Royal Academy of Turin will award a prize, in 1886, of $900 to the author of the best work that appears between 1883 and 1886, on any subject connected with physics, chemistry, physiology, geology, geography, or statistics, or to the author of a brilliant and useful discovery This prize is open to competitors of all countries

Nephrotomy and Nephrectomy in Minnesota —Dr Berry, of New Ulm, performed the operation of nephrotomy almost two years ago, with success Dr French, of Minneapolis, performed both nephrotomy and nephrectomy in 1884, and Dr Wheaton, of Minneapolis, has recently had a case of nephrotomy

Adulterations in Quinine —Dr Cyrus Edson, of the New York Health Department, has been buying quinine at forty or fifty drug stores, and the city chemist has discovered that many of the samples are greatly adulterated In some cases the adulteration of what had been sold as a pure article amounted to 50 per cent

Drs Koch and Klein —The *British Medical Journal*, of January 31, in giving a *resume* of Dr Klein's report from India on the cholera bacillus, states that Dr Koch appears to recognize that he has not established the fact that the comma-bacillus is the cause of cholera, and that he proposes to return to India to make further investigations, at the earliest date that his duties in Berlin will permit

Cancer a Frequent Cause of Death in Horses —The *Indian Medical Gazette*, quoted by the New York *Medical Record*, says As in England, melanotic cancer is an ordinary cause of death in Bengal among gray and white horses We can scarcely drive through Calcutta without seeing animals having the characteristic globular tumors beneath the skin

The Secretary of the West Virginia State Board of Health —Governor Jackson has appointed Dr L D Wilson to the office of Secretary of the State Board of Health, *vice* Dr James E Reeves resigned

Isolation of Phthisical Patients in Austria —The Austrian Government has recently ordered that all phthisical hospital patients be isolated, and that such precautionary measures as necessary be adopted against the extension of the disease

A New Medical Journal —The *Eco Cientifico de las Villas* is a semi-monthly journal, which has recently commenced publication in Sagua la Grande, Cuba It is edited by Dr Augustin W Reyes, and is devoted to medicine and agriculture

French Microbiological Laboratories —The French Government has recently sent M P Gibier to Germany for the purpose of studying the organization of laboratories of microbiology

Professor Birch-Hirschfeld, of Dresden, has been appointed to the chair of Pathological Anatomy at Leipzig, the chair made vacant by the death of Professor Cohnheim

The annual meeting of the Louisiana State Medical Society will be held in New Orleans, on April 21, 22 and 23

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDING FEBRUARY 21, 1885

Battle, K P, Assistant Surgeon, to proceed to Pittsburgh, Pa, for temporary duty, February 19, 1885

RESIGNATION

Heath, W H, Passed Assistant Surgeon, resignation accepted, as tendered, by the Secretary of the Treasury, February 14, 1885

PROMOTION

Kalloch, P C, Assistant Surgeon, promoted and appointed Passed Assistant Surgeon by the Secretary of the Treasury, from March 1, 1885, February 19, 1885

CONTAGIONS AND EPIDEMICS IN AMERICA

BY WM MORROW BEACH, M D , OF LONDON, O

The Address of the Retiring President Read before the Second Annual Meeting of the Ohio State Sanitary Association held at Columbus Ohio February 5 and 6, 1885

In the collation of the facts contained in this paper I have drawn from a great variety of sources The first epidemic to which I allude is one usually referred to in histories of the North American continent, and in nearly all monographs upon the subject of ancient mounds and mound-builders, in explanation of the obscurity of their origin, and the theory that the builders became extinct by a great pestilence But the first pestilence on this continent, of which we have undisputed proof, occurred among the Aborigines of the eastern coast, in 1617 How general this epidemic was remains an uncertainty, but in 1618-19 Captain Dermer, an English adventurer, wintered among the Indians, and as he coasted southward in the spring towards Virginia, he stopped in several towns that he had visited the season before He says he found many Indian towns "totally depopulated " In other towns a few remained alive, but not "free of sickness " The disease, he says, was the "*plague*, for we might perceive the sores of some that had escaped, who described the spots of such as usually die "

In a sermon preached in Plymouth, Massachusetts, by Elder Cushman, in 1620, and which was published in London, mention is made of this epidemic He says " they (the Indians) were very much wasted of late by a great mortality, that fell amongst them three years since, which, with their own civil dissensions and bloody wars, hath so wasted them, as I think the twentieth person is scarce left alive "

This epidemic spread along the coast from Naraganset to Penobscot Plymouth settlers who went to Massachusetts bay to buy corn, "found among the Indians" (in 1622) "a great sickness not unlike the plague, if not the same " The Plymouth settlers found the " bones of many who had died, still unburied "

In 1633 a "pestilent fever" carried off 20 of the Plymouth settlers, and the small-pox appeared among the Indians with great mortality It spread from Naraganset to Piscataqua, and westward to the Connecticut river

In December, 1638, a general fast was observed by the Plymouth settlers, one of the reasons for which was on account of the prevalence of "small-pox and fevers "

In 1647 an epidemic *catarrh* appeared in America There died in St Kitts and Barbadoes 6,000 each

In 1655 appeared the second epidemic of catarrh It was general in New England

In 1659 the *cynanche trachealis* prevailed

The legislature of Connecticut, in 1662, appointed a day of supplication " for the abatement of the sickness in the country" and " a supply of rain in time of drouth "

In 1666 the small-pox raged in Boston , and sickness, attended with great mortality, in New York

In 1667 the small-pox prevailed in Charlestown, Mass , with the mortality of a plague

In 1678 the small-pox prevailed in Boston, malignant diseases were general, and a blight fell upon fruits

In 1692 a malignant fever visited Jamaica and Barbadoes, upon which islands 3,000 in each perished in that year

In 1693 the fleet, under Sir Francis Wheeler, which was sent for the subjugation of Martinico, was seized with the "American plague" (doubtless yellow fever) and three-fourths of the seamen and soldiers perished

In 1697–98 an epidemic *catarrh* was general, and *pleurisy*, as an epidemic, followed in 1698

In 1699 in Charleston, S C , and in Philadelphia the *yellow fever* raged with unprecedented mortality It was called the " Barbadoes Distemper " The patients "vomited and voided blood " In Charleston the " principal officers of the government, one-half the members of the assembly, and many citizens died " This disease appeared in August, simultaneously in both places, and abated as winter approached

In 1702 the general court of Boston adjourned to Cambridge, on account of the mortal small-pox, in Boston "attended with a sort of scarlet fever " In this year the assembly of New York met at Jamaica, Long Island, on the account of the prevalence and great mortality of yellow fever in New York city It was called the "great sickness," and scarcely a patient recovered

In 1712 epidemic *pleurisy* again prevailed throughout New England , and again in 1719 it prevailed in Hartford, Conn

In 1720 the *yellow fever* devastated some of the towns in the State of Delaware, and, in 1723, in Martinico and Barbadoes

In 1723, in Rhode Island, prevailed the " *burning ague*," as mortal as a plague, and in 1728 *yellow* *fever* in Charleston, of a pestilential type, and malignant measles and epidemic *pleurisy* in portions of Connecticut and Massachusetts

Small pox was in Boston in 1730, and in 1731 in New York, as epidemics

In 1732 epidemic *catarrh* was universal in America, and the following year spread over the whole earth

In May, in 1732, appeared at Kingston, New Hampshire, a disease among children, commonly called "*throat distemper*" The disease was very malignant, with swelling of the throat, with white or ash-colored spots, an efflorescence on the skin, great debility of the whole system, and a tendency to putridity Of the first forty patients *all died* In August it appeared in Exeter, in September, in Boston, fifty miles distant, and continued to spread from place to place through that and the succeeding year, and passing to the southward it literally *stripped the country* of children Although *very infectious*, yet it spared not the most sequestered spot, without any possible communication with the sick In many families all the children died It spread westward as least as far as the Hudson river In 1737, while this *angina maligna*—for such it doubtless was—was spreading over the northern part of America, yellow fever was prevailing in Virginia, and epidemic *influenza* became universal—prevailing also in the West India Islands

In 1739 the small-pox was in New York, and the yellow fever in Charleston, followed by measles over the whole continent

In 1740 yellow fever was in Philadelphia and Virginia, followed, in 1742, by a universal epidemic of *angina maligna*

In 1743 yellow fever again prevailed in New York, and in 1745 it was in Charleston, S C In this same year a malignant *dysentery* carried off *seventy* persons at Stamford, Conn and one of the peculiarities of the epidemic was that it was confined *to one single street* In this same year Albany, N Y, was visited by a malignant fever, in which some of the patients turned yellow, and many who recovered were *left imbecile* The Mohican Indians suffered severely by the same disease Dysentery, of an epidemic character prevailed, also, in many localities

In 1747 epidemic catarrh became universal, while yellow fever prevailed in Charleston and Philadelphia

In 1749 dysentery and the "*nervous long* fever" prevailed in Connecticut, with great mortality This was probably what we now call *typhoid fever* It was then considered contagious, but there were many who had it contracted it from "the pestilential condition of the atmosphere"

In 1751 *dysentery*, in an epidemic form, and also *angina maligna*, became general, and prevailed for several years

In 1755, in one town on Long Island, but two children were left alive—all else having died of *angina maligna*!

In 1760 *pleurisy* was again epidemic in Connecticut, and in 1762 yellow fever prevailed in Philadelphia

In 1763 the Indians on Nantucket and Martha's Vineyard suffered severely by yellow fever—two-thirds of their whole number dying in that year

In 1770 angina maligna prevailed from Boston to Jamaica and West India Islands, followed in 1772 by epidemic catarrh

In 1773 measles became general, and was characterized by secondary fever and tedious convalescence, attended with excessive expectoration It seemed "that some discharged to the amount of their weight"

But the most fatal disease was the *cynanche trachealis*, or "bladder in the throat" In general there was little canker, but excessive bronchial and pulmonary secretion—very tenacious, and generally fatal In some towns but few recovered This was followed by an epidemic of *dysentery*, which was very fatal, ending in gangrene on about the third day

In 1774 *scarlatina anginosa* was in Philadelphia, and in 1775 *cynanche trachealis* spread all over the northern part of America

In 1776 epidemic *dysentery* appeared among the troops at New York and Ticonderoga, and in 1777 there were 4,000 cases of small-pox among the soldiers at Crown Point, Vermont From this time on until the close of the Revolution, epidemics of *measles*, *scarlatina* and *angina maligna* prevailed to a greater or less extent Measles, in New England, was of a very malignant character—usually of the kind called "black measles," and inclining to gangrene and putrescence My impression is that this and some other diseases assumed the putrescent type, from the habitual use of *corn bread*, the grain of which did not fully mature in New England, but more particularly the habitual use of *rye bread*, in which flour there was a mixture of "blasted rye," or ergot

In 1789 epidemic *influenza* became so general that it spread even to the solitary Indian in his hut in mid-wilderness In Philadelphia, according to Dr Rush, this influenza, in September, seemed to swallow up or absorb the prevailing scarlatina anginosa, but as winter approached it was succeeded by the scarlatina The scarlatina which was epidemic in Philadelphia in 1789, did not reach New England until 1791, before which time it had been little known in that part of the country

In 1790 *catarrh* again became universal, and in the following year it assumed a type of great severity in Pennsylvania and Virginia In this same year, 1791, yellow fever reappeared in New York, and the remittents in Philadelphia assumed a type like hepatitis, as though the disease was modified by, or was possibly a full cousin to the prevailing yellow fever of New York

In 1792 yellow fever was again in Charleston, S C, and *scarlatina anginosa* was general in New England

In 1703 in Philadelphia, appeared *influenza*, *scarlatina*, and mild *remittents*, in the order named, and late in summer they all disappeared or were *merged into* the prevailing epidemic of yellow fever The latter disease carried off 4,040 persons in that season in Philadelphia alone

In 1794 the yellow fever appeared in New Haven, Conn., and spread along the coast, but in the following season, 1795, an epidemic *dysentery* carried off more people than had died of yellow fever during the preceding season.

In 1796 epidemic *dysentery* prevailed in Wilmington, North Carolina, which seemed to merge into, or was succeeded by, yellow fever. Yellow fever also prevailed in Charleston, Philadelphia, New York city, Newburyport and Boston.

In 1797 it was again in Charleston, Norfolk, Baltimore and Providence, Rhode Island. In this same year, *pleurisy* and *peripneumonia* became epidemic in some localities. In this same year *dysentery* was experienced in Portland, Maine. Some had yellow bodies, but, as some lived as long as thirty-six days, it is presumable it was an epidemic of dysentery assuming a typhus or malignant form.

In 1798, catarrhal fevers were general during the spring months, but later in the season, the most general epidemic of *yellow fever* that has ever visited this country supervened. It appeared in Philadelphia and in Boston in June, and did not break out in New York until August. This epidemic was not confined to cities, towns or villages, but became *general*, and in New York, toward its close, many had buboes and carbuncles, as in *true plague*. In New York 2,000 died of the disease, and it was everywhere esteemed *contagious*, although it had spread without any known means of communication unless it was the pestilential condition of the atmosphere.

The "jerks" first appeared at the "Cane Ridge" camp-meetings, in Kentucky. Peter Cartwright, the eminent pioneer of Methodism, says in his autobiography, that at Cane Ridge sometimes as many as 2,000 persons would all be jerking at once. Lorenzo Dow leaves a vivid description of it as it appeared in Tennessee. In clearing off a camp ground for one of the meetings he held there, the people cut off all the saplings about six feet high, leaving the stubs *to jerk by!* His description of it at Knoxville, Tenn., bears date of 1803, but it appeared at Cane Ridge earlier. This singular disease did not seem to arise from the exaltation of religious fervor or excitement, for scoffers were often the first ones seized, and the most violently affected. The disease became somewhat general, I suppose, as I have heard my mother describe how the women's hair combs would fly, and how their hair would *crack*, like the ox man's whip! and her knowledge of it was as it appeared to her in the province of Maine, I suppose, for she was there during her childhood. The latest epidemic of it, of which I have any account, was in McLean county, Illinois, in 1866, a description of which was sent me by a personal witness at that time.

The Asiatic cholera visited us in 1817-19, and again in 1832. The latter visitation appeared at Quebec, June 8, 1832, at Montreal, June 10, and thence pursued a rapid course up the St. Lawrence to the Great Lakes and the Valley of the Mississippi. Another column of it attacked New York on the 24th of June, and in its northward march laid siege to Albany on the 3d of July. The southward column, from New York, spread down the Delaware and Chesapeake bays, reaching Philadelphia on the 5th of July, and Baltimore in the course of the same month. In November it appeared on an island off Charleston, S. C., in February, 1833, in Havana, and before the close of the year it had overspread Mexico.

From 1841 to 1846, an epidemic of erysipelas of the throat, usually called "black-tongue," spread all over the United States. It was not infrequently complicated with pleurisy, peritonitis, meningitis or pneumonia. It was generally of an asthenic character, attended in some cases with œdema of the glottis and larynx, and suppuration of the glands of the throat.

The Asiatic cholera again visited us in 1848, invading New Orleans by way of immigrant ships from Havre, France. It spread along the Mississippi river, one column marching westward from St. Louis along the great overland route to California, strewing this obscure highway with the bones of more than 1,000 of those adventurous argonauts, besides other hundreds of Indians who were attracted along the route from curiosity. Another column marched eastward from Cairo, along the Ohio, reaching central Ohio about June, 1849.

During this epidemic 5,000 persons perished of it at Kingston, Jamaica, and in that island its devastations reached to Radner, and at other points in the parishes of Port Royal and St. Andrew,—3,000 feet above the level of the sea. In 1849 it prevailed here in the city of Columbus, and among its victims were Doctors Taylor, Gard and Butterfield,—physicians who stood at the head of the profession. In the months of June, July and August, 1850, there were *fourteen hundred* deaths by it in Cincinnati alone. In Ohio the epidemic, in many localities at least, invaded the country districts. In the village of Amity, Madison county, and its surroundings, about one-fifth of the population perished within three weeks.

The deaths in the United States probably reached 200,000, and it did not disappear entirely until after 1855.

In 1853 an epidemic of *yellow fever* prevailed in the lower Mississippi Valley. At New Orleans, in June, July and August, there were over 16,000 cases in the different hospitals alone, of whom over 8,000 died.

During the time of the civil war our armies were generally spared from any scourges from epidemic causes. This seems unaccountable, especially under some circumstances—as, for instance, within the stockade at Andersonville. There, from March, 1864, until April, 1865, 49,485 prisoners were received. The largest number in at any one time was 33,006. A small stream running from west to east passed through the inclosure. The borders of this stream soon became a quagmire, and there was drawn a line around the entire inclosure, nineteen feet from the inside of the stockade. This was the "dead line," beyond which none might pass without being summarily shot. Deducting the quagmire and the space beyond the "dead line," there remained to 30,000 prisoners about seventeen square feet to the man. A small shed, covered, but never inclosed, was the only shelter ever furnished for all these thousands within the stockade That these unfortunate thousands did not fall victims to some sweeping pestilence seems to set at defiance all known laws of health, but while 12,962 were carried out for burial, 3,952 are reported as having died of diarrhœa, 3,574 of scurvy, 1,648 of dysentery, *1,268 of unknown causes,* of anasarca 377, typhoid fever 229, pneumonia 221, debility 198, intermittents and remittents 177, *gunshot 149*, pleurisy 100, bronchitis 93, rheumatism 83, varioloid 63, gangrene 63, catarrh 55 ulcers 51, and phthisis 36

At Wilmington, North Carolina, just before the war closed, 10,000 of our men were brought in from Confederate prisons They were carried by rail, and when night approached the trains were stopped and the prisoners *corraled* until morning From one train load, on the night before reaching Wilmington, 30 were left dead in the *corral* At Wilmington, those who were able for transportation were sent north, whilst the others were cared for in and around the city An epidemic—somewhat like a *typhus*—sprung up in the city For over a month the death rate was about 120 a day—60 soldiers and 60 citizens! This disease followed our moving columns out into the country At Goldsboro, Raleigh and Salisbury, within about one month I had about 140 soldiers detailed as division hospital nurses, *not one of whom*, I think, escaped from contracting the disease

As a sample of its occasional malignancy, I recall one case Dr W A Spain, of the 80th Indiana Volunteers, who had but recently gone on duty at division hospital, approached my tent one day and said, humorously, that a new nurse from his regiment was certainly a *character* The nurse had taken him into a tent, and carefully removing his shoe and stocking, had shown him an eschar reaching obliquely across his entire instep, which he said he had voluntarily made to avoid going into battle Another eschar was shown which he said was made for like purposes, on another occasion Upon which he deliberately drew on his stocking and shoe and went off to his duties I told the Doctor that I supposed the case he had described was similar to several I had seen in the hospital—and that most likely—as the eschars were old and white—they had been received in childhood,—that his temperature was probably as high as 110°, his pulse frequent and weak, and his death not more than thirty-six hours ahead The man was found on duty, after a long search for him, and my predictions found to be true as to disease,—and the second morning thereafter he was buried

In 1866 emigrant ships again brought *Asiatic cholera* from Havre to New York It spread all over the United States, and as far west as the Smoky Fork, in Kansas

The next great epidemic was of *yellow fever*, in 1878 It spread along the Mississippi valley, from New Orleans as far north as the Ohio river, and up Gallipolis It was not confined to the cities along phia- sissippi river, but invaded towns, villages and In 1, and even the laborer and his family, in the most sequestered places in Louisiana, Mississippi and middle and western Tennessee, were stricken by the disease Probably 30,000 persons, in all, were affected by the disease

During the winter of 1881–82 small pox prevailed as epidemics in San Francisco and Chicago A number of cases, in each city, that proved fatal, were in persons who had had previous attacks and were left badly marked by the first seizure

In 1882–83 it was epidemic in Cincinnati, where about 4,000 cases occurred, with an aggregate of 1,600 deaths

* * * * * * * *

I think it *impolitic*, as well as dishonorable, for sanitarians to claim too much power in the avoidance or suppression of epidemics Diseases that are *infectious* alone are always avoidable, and most diseases that are *exotic*, by proper caution and untrammeled liberty of action, can be prevented from obtaining a foothold at any point along our coast or on our borders But there seems to be a subtlety about scarlatina, diphtheria, epidemic cerebro spinal meningitis, and a few others not yet fully comprehended, and all are probably *endemic*

As to measles, whooping-cough, chicken pox and mumps, they are among our milder contagious, and should probably not be avoided at all, unless it is for the purpose of postponing an attack until a more favorable part of the season They are usually considered as diseases of childhood,—probably from the fact that they are easy of communication, and not avoided as other more deadly contagions are, and so overtake us before we are out of childhood, and, possibly, because they may be *spontaneously originated*, and then become epidemic

It was probably demonstrated to the satisfaction of most surgeons, in the late civil war, that measles could be and often was *originated* by placing soldiers to sleep on damp straw But whatever are the facts connected therewith, I look upon it as being as much the duty of parents to see their children safely through these common contagions, as to care for them through their period of teething, or to see to their education, or any other parental duty that fits them for the great battle of life It should be looked upon as *destiny* to suffer from these milder contagions at some time in life, and as fewer die of them in childhood, in proportion to numbers, than die of them after maturity, it is better to have them in childhood, when loss of time counts for nothing, and home nursing is assured, than to wait until maturity, when, if the attack be fatal, the cost of raising would all be thrown away!

That *yellow fever*, of a sporadic character, sometimes originates in the United States, is probable, but if these sporadic cases are *genuine yellow fever*, there is no evidence that any of them have ever proved *foci* for an epidemic, or have ever proven infectious at all At this age of the world, infectious yellow fever is a native of the West India islands, and epidemic Asiatic cholera a native of India

A returned missionary of the Methodist Episcopal church, Mrs Mary A Scott Badley, who had been ten years at Lucknow, told me last year that in India sporadic cases of cholera were *usual*. For instance, a wayfarer, weary, footsore and half-famished, would pluck an over-ripe cucumber from the tree and eat it, and by morning be dead of cholera as the result of his indiscretion; and yet these cases were not considered infectious or contagious, but that epidemics spread from cases occurring in crowded marts or great assemblages,—as they always do from the great congregations of religious pilgrims at Hurdwar.

But, from the careful study of most of the histories of the great epidemics of Asiatic cholera or yellow fever that have been transplanted to our continent, I think that *every one of them was preventable!*

When *once transplanted*, overcoming them or keeping them in subjection becomes quite another question, and may often eventuate in partial failure. The *materies morbi*, whatever they are, seem to become so extremely concentrated, widely and universally diffused, and *pestilential*, that even the birds of the air sometimes either disappear or die.

The safe and sure time to save property from destruction by fire is not when whole cities are ablaze, but before the torch of the incendiary is first applied.

CHRONIC HYDROCEPHALUS.

A CLINICAL LECTURE DELIVERED AT THE GOOD SAMARITAN HOSPITAL, CINCINNATI, OHIO.

BY F. FORCHEIMER, M.D.,

PROFESSOR OF PHYSIOLOGY AND CLINICAL DISEASES OF CHILDREN IN THE MEDICAL COLLEGE OF OHIO.

Reported by James M. French, M.D., Former Assistant to the Children's Clinic.

GENTLEMEN: The clinical history of this child is as follows: He was admitted to the hospital October 11, and was at that time twenty months old. The family history was that the mother, the maternal aunts and uncles, and the grand-parents are healthy; the father died of phthisis. The record of the examination, at the time of admission, shows that the child was very anæmic and badly nourished; that he had a large, square head, and that the fontanelles were still open, the protubera prominent, and the lymphatics generally enlarged. There was observed, also, a prominence of the sternum and lateral depressions of the chest. The liver and spleen were slightly enlarged, and there was a slight curvature of the spine in the dorsal region. There was slight dullness on percussion over the apex of the left lung, bronchial respiration, increased vocal fremitus, and a few râles. The diagnosis then was *phthisis in rachitico*. The child was put upon proper treatment, but without benefit. It was found that the appetite, which had been almost ravenous, began to diminish, and there were slight elevations of temperature in the evening, although there was never very pronounced fever. Never during the whole course of the trouble has the temperature been above 100°. It was further observed that the child's whole manner of behavior was becoming changed. When brought into the hospital, the child was apparently normal in his manners; he did not cry more than a healthy child would cry, he was not fretful; but he has since then become more and more fretful. Instead of sitting up on the bed with the other convalescent children, and playing with them and the other rachitic children in the ward, this child preferred to be alone. He would lie down and could not be kept up; so he was finally put into his crib and kept there. It was then noticed, upon more careful examination, that the pupils reacted in a peculiar manner. They began to react very poorly to the stimulus of light. They would no longer contract to their fullest extent, but after contracting to a certain degree, their contractility would cease.

Furthermore, as the child's head was very large when he first came under observation, we began to take measurements of it; and we discovered that, whereas, on the second of November, the head measured just 48 centimeters in circumference, on the ninth of the same month it had increased one centimeter, and ever since the circumference has gradually but steadily increased. The child has been put, as I have said, upon what we consider the proper treatment, but with no effect. He has lost steadily in weight. The bowels, instead of being loose, as is the rule in rachitic children, have now a tendency to be constipated, so that it is with difficulty that he has a passage. In other respects that I shall show you, the child has been behaving in a manner that indicates but one thing; and what that is, we shall now see.

Those of you who remember seeing the features and expression of the child some time ago, when I brought him before the class, will agree with me that he has lost a great deal since he was here before. The first thing that strikes you is the intense anæmia. The skin, instead of being a beautiful pink, as a child's skin should be, is almost colorless; it is waxy. The child is also intensely emaciated. You see, too, all the evidences of rickets, the chicken breast, the enlarged abdomen, and prominent epiphyses everywhere. But what we wish to examine especially is the head of the child. You see the peculiar form of the head. I find upon examination that the fontanelle is still widely open, and that I can feel very distinctly the sutures. Upon measurement of the head, now, I find that it is 18¼ inches in circumference, whilst the circumference of the thorax is only 14¼ inches. That gives you a correct idea of the relative sizes of the head and chest; but you must not forget that the circumference of a child's head at that age is normally somewhat greater than that of the thorax. Nevertheless, there is normally no such difference as you see here.

You notice that the child has his hands up to his head all the time; I take the hands away, and they immediately go up again. You look at the child's face and you are at once struck with the fact that it takes up much less of the outline of the head than it should. The greater part of the face extends from the eyes up; in other words, the child's head is too large. You are probably aware that an artist, in drawing a typical face, draws first an oval outline. This he then divides, by a straight line running parallel to the long axis of the oval, into two equal parts. This straight line he then divides into two parts by a transverse line through its middle, and upon this last line he places the centre of each eye Now, if he were to draw a hydrocephalic head, what would he do? He would simply lengthen the distance from the eyes to the top of the head, or the upper extremity of the oval, as I do in this drawing on the board I have had an instrument constructed for the purpose of measuring these heads It is an instrument of brass, the perpendicular rod of which is graduated to fractions of an inch, and, fitted to it, is a sliding bar that moves freely up and down The method of using the instrument is to place the upper part on the child's head, then slide this movable part up or down until it is exactly opposite the middle of the eye I then know, of course, what the distance from the chin to the top of the head is, and from the top of the head to the eye, and deducting the one from the other, I have the difference, if there is any, between the two In the case before you, the whole distance from the top of the head to the chin is 6 inches, the distance from the top of the head to the middle of the eye is 3⅜ inches, the distance from the middle of the eye to the chin is, of course, the difference, or 2⅝ inches We know then, from this examination, that the upper part of the head, the skull, is much too large in comparison to the lower part

I have just called your attention to the fact that this child is constantly sitting with both hands raised to his head, he has either one hand supporting the head and the other in his mouth, or both hands supporting the head In addition to this, he cries constantly, but another thing you will observe is that he never moves his head Upon examination of the eyes, we find, in the first place, that there is a slight amount of photophobia, and, in the next place, that the pupils do not react at all to light There is no abnormity in the position of the eye

I am particularly glad to be able to call your attention in this case to a peculiar symptom which has attracted a good deal of attention, and whose value has elicited not a little discussion It is, however, a peculiarity to which I have called your attention in connection with other cases If I draw my finger over the skin of this child's thorax or back, there very quickly comes out a red line which gradually disappears, it is known as the *tache rouge*, or Trousseau's spots

You hear this peculiar whine? The child keeps that up day and night It is interrupted only by an occasional short lapse Sometimes after a sleep the child awakes with a loud and very peculiar, shrill cry

The question now is, what are we dealing with, to what is the trouble due, and how can we explain some of the symptoms? The disease is known as chronic hydrocephalus—an accumulation of serous fluid, comparatively poor in albumen, rich in potassium salts, rich in phosphates—that is found in the ventricles of the brain, and sometimes in the subarachnoid spaces The great majority of cases that come under our observation are of that class in which the fluid is found only in the ventricles When it is found in the ventricles the disease is called *hydrocephalus chronicus internus*, when it is found outside of the ventricles, in the subarachnoid spaces, it is called *hydrocephalus chronicus externus* I am willing to admit that I have never been able, clinically, to separate these two classes of cases, I have never, as yet, seen cases in which I could separate an internal from an external hydrocephalus, so that I shall have to discuss the subject with you as an entity

This child presents to you such interesting features of beginning chronic hydrocephalus as you may not see again for years What makes me think that this child is suffering from this disease? The chain of symptoms that I have described to you is sufficient to justify me in that belief In the first place, and principally, the enlargement or dilatation of the child's head That is proof positive that the child is suffering from hydrocephalus Is such a thing possible as a child suffering from hydrocephalus without a dilatation of the head? Such a thing is possible, but of course it can occur only after the bones of the head have thoroughly ossified Then the dilatation goes on at the cost of the brain substance The fluid accumulates in the ventricles, presses upon the brain substance and causes it to occupy much less space than it originally did Of course in such a case the diagnosis becomes very difficult, but in a case like this the diagnosis is easy This child, when he came in, had a large head, but it has been proved by measurements that it has, since that time, increased very much in size, and it is still increasing

To what else could this condition be due? To nothing else, this is either hydrocephalus produced by an inflammatory active condition, or hydrocephalus produced by a passive condition What other symptoms have we that lead us to this conclusion? We have all these symptoms that I have described, we have the change in disposition, we have the change in the reaction of the pupil, we have the child suffering pain, and suffering in all probability from headache, which is indicated by his constantly putting his hands into his mouth These are all corroborative symptoms of the changes going on in the head This change of disposition is by no means a constant symptom I have now in my care a child with hydrocephalus that is apparently healthy and, if anything, more jolly than children usually are, and in which there are none of these manifestations The cases vary in regard to the symptoms they exhibit, these depending largely upon the amount of inflammatory change that is going on in the ventricles or in the meninges If there be very great inflammatory changes, if there be a great deal of pressure, then of course these symptoms will be more pronounced If, on the other hand, the child is born with too much fluid in the ventricles, there will not be many symptoms produced

Another feature that I want to call your attention to more fully, is the fact that this child does not move his head During the whole time that he has been sitting here, fully half an hour, he has not taken his hands away from his head, or moved his head in the least When he is in his crib with high sides, he either supports his head with his hands or leans it against the sides of the crib The explanation of this peculiarity is simple It is because the child's head is too heavy for him I want you to remember these facts, for they are almost characteristic of the disease

In regard to the other symptoms, it is not necessary for me to detain you long Usually there is some derangement of the alimentary canal in these cases, the children suffering from constipation, as this child does If the patient has had rickets and then becomes constipated, while it has other symptoms of hydrocephalus, this change will aid you in the formation of a diagnosis

What is the cause of the hydrocephalus in this child? Tuberculosis Tuberculosis produces hydrocephalus in several ways I have shown you that the child has tuberculosis of the lymphatic glands, the so called scrofulosis All the glands of the child are very much enlarged This may act in very many ways First, the circulation of the lymph in the brain may be disturbed, so that we may have an exudation of lymph in the subarachnoid spaces or in the ventricles Then the glands of the neck may be enlarged, and by pressing on the veins cause a transudation of the fluid elements of the blood In the next place, the tubercular virus may undoubtedly cause chronic changes in the membrane lining the ventricles, in this way cause chronic inflammatory changes, and thus produce hydrocephalus Which of these methods have been the cause of the disease in this case, I am unable to state Is tuberculosis always the cause of hydrocephalus? By no means I am speaking now of chronic hydrocephalus Acute hydrocephalus, you remember, is synonymous with tubercular meningitis, but chronic hydrocephalus may be produced by a number of diseases, as by a tumor of the brain Acute inflammations that become chronic may cause the disease, an acute meningitis may become a chronic meningitis It is claimed that syphilis has something to do with the production of a chronic hydrocephalus, but with regard to that and the production of the congenital form of the disease, we know but little Sometimes the disease is due to uræmic poisoning

The prognosis is, in the great majority of instances, bad Can you in an individual instance make a prognosis? Yes I should say that in a case of this sort the prognosis must necessarily be bad There are cases, however, in which, even after the exudation has become enormous, the child is reported to recover Perhaps some of you have seen cases in which the exudation has become so great that the head has gotten entirely beyond the control of the child, so that it has to be moved about by another person, and in which the child lives and gradually recovers After such a recovery there is, of course, a good deal of deformity I shall never forget the simile used by one of my teachers He said that he had a case of a child with an enormous head, that got well and grew to womanhood, but that her head looked like a raised map of Switzerland The exudation being absorbed, the head contracted, but the sutures remained raised You must, however, be on your guard about your prognosis

The treatment is to allay symptoms My treatment in this case is to give opium I give to a patient like this sufficient opium to keep him quiet As soon as I find that this irritable state has disappeared, if it does disappear, I give internally iodide of potassium, regulate the bowels, and of course try to remove the cause If the disease is due to uræmia, or if, in the course of a case of uræmia that you are treating, symptoms of hydrocephalus supervene, you must treat the case accordingly I have not much faith in puncturing these cases, although it sometimes seems to give relief I have no faith, either, in compression, for I have seen no good results from it

---

THE HONORARY DEGREE OF DOCTOR OF MEDICINE

BY E INGALS, M D, CHICAGO, ILL

The ordinary degree of Doctor of Medicine is conferred by an institution of competent authority on persons who are supposed to have acquired, by diligent study and careful instruction, a sufficient amount of medical knowledge and skill to constitute them safe practitioners of the science and art of medicine The attainments of the person applying for the degree are ascertained by a proper examination, conducted by the teachers in the institution by which the degree is given The possession of the degree is evidenced by a diploma, which, after the person who holds it has complied with certain governmental requirements, assures to him all the rights and privileges of a member of the medical profession But such institutions may also confer, *without an examination*, the additional honorary degree of Doctor of Medicine on persons already in the profession, who have publicly demonstrated their attainment of such a degree of learning and skill in medicine as would make the conferring it on them to be an act of such undoubted propriety as to be acknowledged without question by all I bring this subject to public notice because the oldest medical college in this city has recently, on two different occasions, bestowed the honorary degree of Doctor of Medicine on a dentist Neither of these persons—if I am correctly informed—has ever made medicine a special study

Both are gentlemen of excellent character, and have been long and well known as skillful practitioners of dentistry I do not, however, understand that these qualities authorize any medical institution to confer the degree of Doctor of Medicine on their possessor

Dr Barnum, D D S, of New York, who hit upon the happy device of the rubber dam rendered a great service to the profession of dentistry, but it would be grotesque and incongruous to bestow on him, for this reason, the honorary degree of Doctor of Medicine With equal propriety it might be claimed by the plumber and optician The medical degree already has too low a rank, and instead of adopting methods still further to degrade it, our institutions of learning should try to elevate it to a position more worthy of esteem and confidence This can be done by conferring it only on persons of good character and high attainments It would be interesting to know how our State Board of Health would treat such an honorary degree, should the diploma be presented for registration Under the rules of the Board I do not see how they could consistently do otherwise than recognize it A professional innovation, wrong in principle and tendency, like this under consideration, should not be suffered to pass without protest, lest in time it might claim to be recognized as an established precedent

34 Throop street, Chicago

MEDICAL PROGRESS

OBSTETRICS AND GYNÆCOLOGY

COMPLETE PROLAPSUS OF THE UTERUS, NINE LARGE CALCULI IN THE CONCOMITANT CYSTOCELE —Dr Varnier (*Progres Medicale, Archives de Tocologie*) gives the case of a laundress, 68 years of age, who in 1875 was operated upon for prolapsus of the uterus The tumor reappeared in time, gradually enlarging until it became as large as the fist She passed through the vagina four calculi of the size of a chestnut, and, becoming alarmed from that circumstance and the severity of the accompanying pain, she entered the hospital Cochin in 1884 On her entrance, an examination established the presence of a vulvar tumor, pear-shaped and of the size of a child's head The anterior portion of the mucous membrane was rose-colored, and ulcerated in places, it was made prominent at one point by a calculus which was readily felt Pressure at that point was extremely painful, and disclosed the presence of several calculi contained in the cystocele At the superior and slightly lateral surface of the anterior portion of the prolapsus there was a vesico-vaginal perforation of the size of a one-franc piece, through which the urine passed constantly Two or three days after entering the hospital, the patient passed a calculus the size of a walnut through that opening On performing cystotomy, four calculi were removed, varying in size from an egg to a chestnut The wound was drained by a catheter kept in the urethra The results of the operation were very good, the wound being healed on the eighth day, but the urine remained purulent and the patient died at the end of five weeks after the operation The autopsy showed that the base of the bladder and the trigonum had followed the vaginal wall in its prolapsus The ureters opened into the cystocele The vesical mucous membrane, as well as the ureters, presented the lesions of chronic cystitis The kidneys were riddled with miliary abscesses, the cortical substance being almost entirely destroyed Chemical analysis showed the calculi to be composed principally of the phosphates and carbonate of lime

Dr Varnier draws the following conclusions from a study of the case 1 The complication of calculi with a vaginal cystocele is not very rare 2 The production of a vesico-vaginal fistula under these circumstances is extremely rare 3 Operations for the relief of cystocele are not so harmless as many writers would have us believe

A NEW EXPLANATION OF THE MENSTRUAL PROCESS —Under this title Lowenthal (*Archiv f Gyn*, *Arch de Tocologie*), before giving his own views, sums up very comprehensively the various opinions of the present day upon that series of phenomena which we class under the term menstruation What may be considered as established, are the following

1 The bloody discharge returns periodically

2 The form and duration of the flow of blood varies essentially with individuals

3 The menstrual blood is identical with that from other parts of the body

4 There occurs in the uterine mucous membrane certain anatomical and histological modifications (*a*) The thickening of the mucous membrane from two or three mm to five or seven mm takes ten days before the discharge of blood to reach its maximum This resembles the formation of the decidua in the first stages of pregnancy, certain round cells being present in both (*b*) During the flow of blood, the superficial layer of the tumefied mucous membrane is destroyed, retrograde hyperplasia, the epithelium of the superficial layer reforms, and, in nine or ten days after the onset of the hemorrhage, is ready with a few days' interval to take on tumefaction anew (*c*) The tumefaction of the mucous membrane occurs especially in the superficial layers, which become more lax, softer, and œdematous This is particularly the work of the glands and lymph spaces, in the beginning the blood-vessels play no part in the process It is only later, when the tumefaction is at its height, that the blood-vessels develop and fill up, that is to say, immediately before the occurrence of the hemorrhage The tumefaction is never the result of congestion, the congestion is never the primordial phenomenon (*d*) Only the mucous membrane of the body of the uterus takes part in this tumefaction The cervix remains free from the process

5 All the other genital organs, and the organism in general, are more or less affected by the menstrual process, but it is in the ovary that the most marked modifications occur

From these facts the author concludes that the menstrual process should be divided into three stages

1 A stage of thickening of the mucous membrane, one of hæmorrhage, and one of regression, *de restitutio ad integrum*

2 These three stages succeed each other in a determined and fixed order

3 The duration of these three stages is about twenty days, ten for the first, four or five for the second, and what remains for the third

4 The phenomena occurring in the other parts of the genital organs and in the rest of the organism, and designated as menstruation, corresponds to the second stage, to the flow of blood

Passing in review the various theories of menstruation and its relations to ovulation, the author recognizes three as of prominence

1 *The Classical Theory* —The actual or approaching rupture of a Graafian follicle, determines the menstrual hemorrhage To this theory the following objections are made (*a*) The real onset of the uterine menstrual process takes place ten days later (*b*) The menstrual blood can come only from a

mucous membrane that is already tumefied, as the vascular congestion does not occur primarily in relation to the tumefaction (*c*) The neck of the uterus takes no part in the tumefaction or in the hæmorrhage, which would be inexplicable if the process going on in the uterus was due to hyperæmia consequent upon ovulation (*d*) Perfectly normal ovulation, followed by fecundation, occurs without a discharge of blood (*e*) A single coitus occurring some time after the cessation of the flow of blood, and consequently after the supposed discharge of the ovule, suffices to produce fecundation

2 *Loewenhardt's Theory* —The fecundated ovule belongs to the next menstrual epoch The ovule is discharged before the menstrual flow occurs If it is fecundated immediately, there is no menstrual flow If it is discharged from the body, the flow occurs There are two varieties

First Variety —The discharge of the ovule does not take place until after the formation of the menstrual decidua (immediately before the flow)

Objections —(*a*) In this case there would be no plausible reason for the occurrence of the tumefaction of the uterine mucous membrane nearly ten days previously (*b*) If the ovule, which is fecundated immediately after its discharge, takes several days to reach the uterus, it cannot prevent the regression of the decidua, or the hæmorrhage (*c*) It is the coitus nearest to the cessation of the hæmorrhage which is the fecundating coitus, for it cannot be admitted that the spermatozoa can dance attendance for twenty days around the ovule

Second Variety —The discharge of the ovule occurs at the beginning of the formation of the decidua (about ten days before the flow)

Objections —(*a*) The diminution in size of the volume of the ovary, which can only be explained by the rupture of the follicle, has never been observed but in connection with an ulterior flow of blood (*b*) The premenstrual physical and mental disturbances, that have been considered the phenomena concomitant with the development of the follicle, occurs always before the hemorrhage and disappears with it (*c*) A periodical rupture of the follicle has never been noted as occurring at the beginning of the formation of the menstrual decidua (*d*) Coitus practiced a long time after the commencement of the tumefaction of the uterine mucous membrane and even immediately before the approaching epoch may be fecundative and suppress the flow

3 *Theory of Beigel* —Ovulation and menstruation have no reciprocal influence Both are the consequence of genital impulsion

Objections —*a* The menstrual process is periodical, whilst the cause to which it is here attributed, sexual excitability in the woman, may be produced at any time *b* In case of congenital absence of the ovaries, there is never menstruation, whilst genital excitability is not always wanting *c* When, as the consequence of castration, menstruation is suppressed, the generic excitability may persist intact, or be but slightly diminished *d* All the organs participate in the menstrual hyperæmia The body of the uterus alone is concerned in the hæmorrhage, the neck never, and thus general hyperæmia occurs immediately before the flow, whilst the real onset of the menstrual process commences ten days before

Theory of Loewenthal —This, of course, is discussed at some length, but it is well expressed in the following conclusions

I The periodical hemorrhage which is produced in the genital organs of the woman is not a consequence of the rupture of the Graafian follicle (a rupture which ordinarily occurs at the same time), but is due to the disappearance of the tumefaction of the uterine mucous membrane, a tumefaction which is independent of that rupture, and which is produced before the hemorrhage

II The menstrual decidua is determined by the imbedding of the last ovule which escapes from the ovary, and remains non-fecundated

III It is formed in the same way as that of the decidua of pregnancy, when the egg which so engrafts itself is fecundated, and it is destroyed after the death of the ovule, when that ovule remains unimpregnated

IV As concerns each isolated menstruation, the rupture of the follicle and the menstrual hemorrhage have no other causal relation to each other than this, that the active causes and circumstances which occur at the moment of the establishment of the hemorrhage are at the same time an occasional cause of the rupture of a follicle

V The coincidence of the rupture of a follicle and the hæmorrhage is not at all necessary Both may be produced independently one of the other A follicle may rupture without the production and regression of a menstrual decidua, and the hæmorrhage, the secondary consequence of the last follicular rupture, may be produced without the simultaneous rupture of a new follicle

VI The periodicity of the menstrual hemorrhage is due to the duration of the extra follicular vitality of the engrafted ovule, which remains non-fecundated The anomalies of this periodicity (general or individual) depend upon idiopathic or accidental influences which determine the lessening or even the absence of this extra-follicular vitality of the ovule

VII Fecundation is produced upon the ovule arising from the follicle which has passed into the uterus, generally at the time of the last menstruation, when it is uterine—or upon that ovule imbedded outside of the uterus, which is exceptional and is extra uterine

From all this come the following practical conclusions

VIII Menstrual hemorrhage is not a physiological function, nor the necessary concurrent manifestation of a physiological function, but the direct consequence, reinforced by innumerable repetitions, of a phenomenon produced by civilization—the non-fecundation and the death of an ovule—it has all the characters and all the influences of other hemorrhages, which are always pathological Like these, and under the same influences, it increases or diminishes

IX The hemorrhage which necessarily accompanies the destruction of the menstrual decidua cannot be considered as inoffensive, except as it occurs by diapederis A hemorrhage by rhexin is always useless and perhaps dangerous, for it becomes a cause of debility to the organism

X The degree of danger is in relation to the quantity of blood lost, and the quantity as well as the quality, is in relation to the blood of the whole body

XI In such cares it is necessary to moderate the menstrual hemorrhage, as with any other hemorrhage

XII The best treatment is rest in bed, and hot injections

XIII On the other hand, the absence of menstrual hemorrhage (idiopathic amenorrhœa) should never be considered and treated as a disease It is simply the proof that a function which is not indispensable to the life of the individual (ovulation), for some cause or other (youth, age, pregnancy, lactation weakness), has not manifested itself, or has not manifested itself at its usual time, that is, at the end of four weeks

XIV Recognizing the importance of the part played by the fallopian tubes in menstruation as given by Lawson Tait, the indications are, in cases of uterine dysmenorrhœa, menorrhagia, fibroma and other morbid processes, which influence the anticipated provocation of the menopause, to practise salpingotomy (resection of both tubes after ligature) instead of castration

XV If, in practising castration for one of the causes cited, the two ovaries are not completely removed, salpingotomy should be performed

ANATOMY AND PHYSIOLOGY

CASE OF MALFORMATION OF THE HEART —In the *Journal des Connaissances Medicales* is to be found the record of a man, 39 years of age, a tailor by occupation, who was affected with epilepsy and died of cerebral disease During his epileptic attacks he was not cyanosed, and gave none of the general symptoms of disease of the heart Cardiac dullness was slight Fremitus most marked at the second intercostal space on the left side A souffle with the first sound over the whole surface of the heart, having its maximum of intensity at the supposed location of the aorta A short souffle with the second sound, at the left intercostal space, near the sternum Pulse irregular The autopsy showed that the aorta was situated in front and to the left of the pulmonary artery, which it did not cross, it had two semilunar valves The pulmonary artery, instead of semilunar valves, was of a cone shape, and truncated above The orifice was narrowed and insufficient The two ventricles were as one, the interventricular wall being absent The auriculo ventricular valves were normal

MEDICINE.

LEAD-POISONING BY SNUFF —Dr F P Weaver reports a case of this character to the Liverpool Medical Institution (Liverpool *Med Chir Jour*) The patient, aged 32, suffered from attacks of colic and difficulty in urinating, the blue line on the gums was found to be present He took snuff in large quantity, Lundyfoot and brown rappee were his favorites A stream of sulphuretted hydrogen, passed through an infusion of the article, gave but a negative result An analytical chemist found lead in considerable quantity in the brown rappee, but none in the Lundyfoot By stopping its use, and suitable treatment, relief was afforded for some years, then a severe attack of colic showed that the patient had returned to the use of equal parts of Kendal brown and brown rappee This mixture was examined by incinerating a portion, treating the ash with water and a little nitric acid, filtering, and then passing sulphuretted hydrogen through the transparent liquid Speedily a black discoloration took place, leaving a large precipitate of sulphuret of lead Separate examination of the two components of the snuff revealed the absence of lead in the Kendal brown, its presence in large quantity in the brown rappee This latter was observed to be a moist snuff, wetting or greasing the paper containing it On buying some of the rappee snuffs at different shops, it was found that both the black and brown varieties were supplied to the retailers in lead foil, and were kept by them in this lead foil in canisters The rappee snuffs from different shops presented the same reaction, all contained much lead

The question arose Was the lead derived from the addition of a salt of lead to the snuff, or from the oxidation of the lead foil in which the snuff was kept? Dr Weaver considers it as derived from the enclosing lead foil, because, *firstly*, the snuff was issued by a first class maker of high standing in the trade, *secondly*, we have the fact of its being actually kept in lead, and *thirdly*, the kind of snuff was that variety, "moist brown rappee," which writers on the subject seem specially to have found contaminated by its wrappers He finds that there are on record thirty four cases of this form of lead-poisoning, and that there can be no question that the long-continued use of moist rappee snuffs brings on insidiously lead-poisoning, causing paralysis of the anus, anæmia, and repeated attacks of colic

COCAINE IN IRRITATION OF THE BLADDER —Mr Edward Bellamy reports that he has used cocaine in cases of irritable bladder, with spasm at the neck of the bladder, with success He uses it in the form of gelatine bougies each containing gr ¼ of the hydrochlorate of cocaine —*Lancet*, February 14, 1885

SURGERY.

A CASE OF PERIODICAL ERYSIPELAS —Dr Cebrian (*Medicina Contemporanea, Le Progres Medical*) gives the case of a married woman, 31 years of age, of a nervous temperament, good constitution and enjoying good health up to the time of her marriage, from which period she has suffered from periodical attacks of erysipelas of the right side of the face Her mother died of black erysipelas in the third month of pregnancy She herself has had three children, whom she nursed The attacks come on with a chill, accompanied by intense cephalalgia and followed by fever The right side of the face is invaded by a vivid redness, which disappears on pressure, giving a burning sensation Between the right and left sides of the face there is a very marked line of separation, commencing at the median line on the forehead, passing down on the median line of the nose, lips and chin, then becoming gradually imperceptible These attacks commenced for the first time with the suppression of the menses which marked the first pregnancy Their periods of invasion, increase and decline conform exactly with the duration and intensity of the menstrual flow, that is, the attacks commence on the day that the flow should appear, and are at their height when the flow should be the greatest, then decline, terminating on the fifth or eighth day This is repeated without interruption to the fourth month of pregnancy, not to return until a new pregnancy occurs Two married sisters suffer in the same way

EXTIRPATION, BY LAPAROTOMY, OF A HYDATID CYST OF THE LIVER —Dr Guttierez reports this curious case in *El Dictamen* (*Le Progres Medical*) A boy, 8 years of age, suffered from a tumor situated in the right iliac fossa and as large as a fœtal head Capillary puncture gave a clear fluid containing numerous hooklets, which were insignificant It having been decided to extirpate the tumor, the right side of the abdomen was opened by an oblique incision, and the tumor dissected from its adhesions to the epiploon, of which a portion was also removed to avoid its mortification After opening the cysts, which had increased rapidly in size after the exploratory puncture, there was discharged with the fluid the great pouch or hydatid, which had as its external envelope the the thickened capsule of Glisson, which the hydatid had by degrees disengaged from the external surface of the liver until it had lodged in the iliac fossa, the operator extirpated the fibrous envelope from its hepatic attachment to prevent any suppuration that might compromise the result of such a brilliant operation He then applied three sets of sutures, very fine catgut, including first the peritonæum, then the divided muscles, and, finally, the skin, using Lister's dressings There was not the slightest trace of peritonitis, but reaction from the effects of the operation was slow, the wound healed perfectly, however, and digestion was normal

MUSCLE GRAFTING —Dr Eduardo Salvia has recently published at Naples a memoir embodying experimental researches on muscle *grafting* (*Lancet*) Gluck was the first to prove experimentally that muscular tissue detached from a living animal has the power, when introduced into the tissues of another animal, of contracting organic adhesions and continuing to live He observed that by adopting certain precautions, chiefly of antisepsis, pieces of muscle, without tendon, might be transplanted in rabbits and hares, and remain in the part grafted as true muscular tissue If, however, the graft excited inflammatory reaction of some *intensity, the* histological characters of the engrafted tissue underwent fibrous metamorphosis Dr Helfreich, in 1882, put this to practical use He removed a sarcoma from the front of the right arm of a lady aged 38 Nearly the whole of the upper half of the biceps was removed, only a small bundle of muscular fibres as thick as a slate pencil being left on the outer side, continuous with the tendon The resulting space was exactly filled with a piece of muscle, weighing three ounces and two drachms, detached from the thigh of a healthy dog just at the moment of grafting Care was taken to ensure accurate adaptation of the muscular surfaces, without hagging, and the grafted muscle was secured to the remaining portion of the biceps with thirty points of catgut suture Some counter-openings were made in the skin for drainage, the external wound sutured, and a Listerian dressing applied The arm, bent at an acute angle, was fixed to the thorax On the ninth day, at the time of the first dressing, in consequence of the detachment of some of the sutures, the lower angle of the wound gaped somewhat, and through it issued a necrotized fasciculus of the engrafted muscle The piece of separated muscle was as long as the canine portion inserted, and about one-eighth its depth On the eighteenth day a piece of skin as large as a shilling sloughed at the point of issue of the mortified muscular fasciculus A month later the patient had completely recovered, but the limb was somewhat œdematous After employing for two months the constant and induced currents of electricity, the right biceps muscle regained its normal electro-motor power, alike on the right side, where a part of the original muscle remained, and on the inner side, corresponding to the engrafted muscle The patient could move the forearm with power, and without the slightest pain, alike in pronation and supination

Dr Salvia, after a number of failures, has succeeded, under strict antiseptic precautions, in engrafting into the thigh of a dog a portion of the rectus femoris of a rabbit So perfectly did the transplantation succeed that no trace of it could be discovered by the naked eye or the microscope when the dog's thigh was dissected three months later Reviewing all the steps of his research Dr Salvia formulates the following

1 It is possible to transplant a piece of the muscular tissue of an animal amongst the cut muscular fibres of another animal, although the two may be of different species

2 The piece of transplanted muscle may become thoroughly united with the muscle into which it is grafted without exciting suppuration or specific inflammation For the attainment of this result it is necessary that the piece of transplanted muscle should completely fit the space resulting from the retraction of the ends in the excised muscle It is equally necessary that the operation be carried out with the strictest antiseptic precautions

3 The union between the fibres of the transplanted muscle and those of the animal grafted takes place by new formation of young muscular fibres, these become immediately continuous with the fibres of the animal and of the graft, without leaving any trace of the primary point of separation

4 The grafted muscular fibres gradually lose their distinctive anatomical characters, acquiring those of the animal's fibres in which they live No difference between them can, after a certain time, be detected by the most careful microscopical examination

5 The function of the muscles after the graft is perfectly restored, and that comparatively quickly, without the slightest indication of weakness or torpor

THE
Journal of the American Medical Association.

PUBLISHED WEEKLY

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information, should be accompanied by the writer s full name and address although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE, INCLUDING POSTAGE

PER ANNUM IN ADVANCE	$5 00
SINGLE COPIES	10 CENTS

Subscriptions may begin at any date The safest mode of remittance is by bank check or postal money order drawn to the order of the undersigned When neither is accessible remittances may be made at the risk of the publishers by forwarding in REGISTERED letters

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 65 RANDOLPH STREET,
CHICAGO ILLINOIS

SATURDAY MARCH 14, 1885

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

Until the commencement of the JOURNAL in July, 1883, the proceedings and papers of the association had been published in one volume, each year varying in size from 500 to 1,000 octavo pages For many years past the annual volume has not reached the table of the members of the association until from seven to nine months after the annual meeting at which the papers, addresses, resolutions, etc , composing its contents had been prepared and presented by their authors By such delay much of the influence upon the profession expected from the proceeding of each meeting was entirely lost, and it became a common remark that few of the papers were ever read except by their authors One of the strong arguments in favor of changing to the publication of a weekly journal, was that it would bring the full record of proceedings of each annual meeting directly into the hands of every member, followed quickly by the important addresses of the President of the association and of the chairmen of the sections, while the important papers relating to all departments of medicine and surgery would follow as fast as the most diligent reader would wish

To enable the reader to judge how far this object in adopting the journal form of publication has been realized, it is only necessary to remind him that the full official record of the proceedings of the meeting in Washington in May last, as prepared by the Permanent Secretary, was in the JOURNAL the second week after the adjournment of the meeting, while the address of the President of the association, and that of the chairman of the section on practical medicine, appeared the same week of the meeting Other addresses and papers followed at the rate of from one to four in each number, until almost all had reached the tables of members by the end of the first six months And it is safe to say they had been actually read by ten times as many medical men as had read the papers in any annual volume of transactions published within the last dozen years And whoever will take the trouble to make the comparison, will find in these addresses and papers both a greater amount and wider scope of matter of direct practical importance, reaching every department of the healing art, and including the results of much important original investigation, than is to be found in the department of original articles in any other weekly journal in this country Many of the papers have been accompanied by numerous and well executed illustrations Besides the papers belonging to the association, the same department of the JOURNAL has contained several valuable contributions from other sources, and many important papers read before other medical and sanitary organizations Every number has contained three or four pages of *Medical Progress*, selected chiefly from the foreign current medical literature, by a special assistant editor in Washington, and most of the numbers have contained interesting letters from regular correspondents in London, Paris and Berlin, as also in Boston, New York, Philadelphia, Cincinnati, and many minor places in our own country

If a less number of pages have been filled with the proceedings of local medical societies in different cities than in some of our contemporaries, it is simply because we had not more space at our command on account of the number and length of the papers of the association, which were entitled to precedence Yet we have given even in the department of local society proceedings, a large amount of very valuable matter from societies in Boston, New York, Philadelphia and Chicago, as well as from some places of less note Prominent attention has been given to sanitary matters, health organizations, and proper principles of medical legislation, and, unless the voluntary assurances of some of the most eminent members of the profession are erroneous, it has already exerted much influence in checking the tendency to social and ethical disintegration, which had been making rapid progress during the few years prior to the commencement of the JOURNAL We shall tax the patience of our readers in one more issue to present the financial progress of the JOURNAL, its present status, and some suggestions concerning its needs and future management

FRENCH JUSTICE IN MALPRACTICE SUITS

The Paris correspondent of the *British Medical Journal* of February 7, states that an action was recently brought by an *Officier de Sante* against Prof Trelat and M Delens M Bouyer, the plaintiff, stated his case as follows In the act of nailing down a box in May, 1883, he slightly injured his left index finger He sent for M Piogey, his neighbor, who was replaced by his nephew MM Trelat and Delens were called in by M Piogey, and the plaintiff complains that a number of operations were performed on him that he was conducted to a *Maison de Sante* and that M Delens applied undiluted alcohol to his bleeding wound, that drainage tubes were used, and camphor dressings bandaged on After six weeks of daily agony he left the *Maison de Sante* with a deformed hand The plaintiff accused MM Delens, Trélat and Piogey of having treated and tortured him against his will, of having injured him by unskillful treatment, and names his damages at 20,000 francs ($4,000)

M Piogey declares that the plaintiff had a deep wound in the left forefinger He sought the help of his nephew, because the patient required constant care day and night Symptoms of septicæmia soon appeared, and it was necessary to call in a surgeon M Bouyer was recommended to M Delens by Dr Pénieres, a deputy He found that very serious lymphangitis had set in, and several collections of pus had formed He prescribed dressings of alcohol in solution M Trélat's services were also secured by a mutual friend The patient expressed gratitude for the care taken of him, and never opposed any part of the treatment, otherwise, his wishes would have been considered M Trelat accepted the responsibility of having M Bouyer removed to a *Maison de Santé*, his condition required it He was in an almost hopeless condition, and could not otherwise have had the necessary attention given to him M Bouyer, the plaintiff, has been condemned to pay 3,000 francs ($600) to each of the three defendants

If some of the common sense evinced by this verdict could be imported for the use of the intelligent jurors of America, malpractice suits would be less common

DYNAMITE INJURIES

The past two years have been rather fruitful of new surgical injuries To the much written of "lawn-tennis back," "lawn-tennis knee," "foot-ball shoulder" and "bicycle perineum," it seems that we must now admit "dynamite injuries" as a peculiar class of surgical lesions Unfortunately, as regards an extensive acquaintance with the peculiarities of this latter class, and unfortunately, also, for the recipients of these injuries, the persons affected by them are more often subjects for a coroner's inquest than for the surgeon's skill

Mr Frederick Treves reports, in the *British Medical Journal* of February 14, 1885, the cases of two sufferers from the dynamite explosion at the Tower of London, who came under his care at the London Hospital As regards the gross lesions caused by the explosion of dynamite, there seems to be nothing special The fractures, lacerations and contusions inflicted by fragments and falling *débris* are very similar to those caused by other injuries But the point of greatest interest seems to be the general effect of the explosion upon the nervous system While it is evident that the body must be concussed or shaken by the explosion, it would be scarcely expected that the effect upon the nerve centers would be identical with the concussion produced by a blow upon the head or the shock caused by a railway collision, the shock from a dynamite explosion seems to be that of a force that is diffused and finely divided It seems that the person affected by it is not hurled to the ground so as to suffer such an injury as may produce concussion in the ordinary clinical sense There is a sensation of being pushed back rather than thrown down

The symptoms in the two cases which he reports may be ascribed, he says, solely to the general shock caused by the explosive, with, perhaps, some superadded emotional influence Neither of them suffered from true clinical concussion, they were not even stunned "Their chief symptoms seemed to have been the outcome of a general enfeeblement of nerve-function, whereby the action of the heart was depressed, the vision dimmed, and the hearing—apart from local changes—dulled It is interesting to note that, in one case, the accident was followed by repeated vomiting " So far as local effects were concerned, the most definite effect was produced upon the membrana tympani

THE TREATMENT OF SEVERE ELECTRIC SHOCK

Dr C G De Schweinitz, of Philadelphia, has recently reported two cases of severe electric shock which recovered under expectant treatment, and an exchange (the name of which we cannot now recall) commends the expectant method in these cases, on account of the fact that we are as yet ignorant of any medical treatment which promises success In the *Medical Record*, for January 31, 1885, Dr W G Eggleston, of Philadelphia, reports three cases of this nature which fully recovered under treatment by atropia and stimulants As may be seen by reference to the latter article, the persons were profoundly shocked and insensible for some hours, that the respiration and pulse were abnormally slow, and that death from dyspnœa or heart failure seemed not improbable, and that these symptoms were relieved and finally dissipated by the treatment adopted

As persons have been known to die from the influence of electric shock some hours after the reception thereof, it seems that any treatment which will relieve the system of its influence should be adopted, and from the prominent symptoms in these cases—dyspnœa and threatened heart failure—there is scarcely a doubt that atropia is a physiological antidote to the influence of electricity, and that its effect is aided by the administration of such stimulants as brandy and ammonia

Apropos to this subject, it may be mentioned that a recent number of *La Lumiere Electrique* states that Prof Dolbear has found that wires carrying currents of high tension may be safely handled if the hands be thoroughly covered with oil With gloves thoroughly impregnated with oil, he thinks that wires carrying a current of 80,000 volts may be touched with safety

COOKERY-LESSONS FOR STUDENTS OF MEDICINE

A recent number of the *British Medical Journal* calls attention to the important part played by the medical profession in the matter of ordering suitable diet for patients, and commends the thoughtfulness which has inaugurated a school of cookery in Edinburgh, in which the medical students in that city may learn how the foods appropriate to the invalid are prepared During the present session this school has given four lessons in the preparation of food and drinks, in the large theatre of the Royal Infirmary It speaks well for the intelligence of the students that these lessons were largely attended and highly appreciated Among other things, the preparation of beef tea, beef jelly, milk-jelly, gruel and milk gruel, and self digested farina were shown, and students were invited to examine for themselves practically the various diets ordered for patients

Such a course for medical students is to be commended in the highest terms, for, apart from the practical application of the knowledge gained in such a school, the time and money here spent is well invested, few things give a physician a firmer hold upon the affections and respect of his patients than a thorough knowledge of what they should eat, and how to prepare it In connection with the cookery-schools we would suggest that students be taught the art of compounding suitable beverages for the sick The physician who knows how to make an eggnogg or a milk-punch is often an important factor in a community

STATE SANITARY INSPECTION

The Illinois State Board of Health has inaugurated a system of inspection of houses and premises which, if carried out, will put them in possession of most valuable data for present or future sanitary work

The circular recently issued by the Board promises that whatever may be done in anticipation of an epidemic of cholera will be equally serviceable for the restriction of other filth diseases

The proposed plan is to make a systematic report of the hygienic features of every piece of property, accompanying it with a diagram of the same Blanks are provided for this purpose, which, when filled out, are to be preserved by the local health authorities, by whom the work is to be prosecuted Tabulated and condensed returns are to be made to the State Board of Health

This plan, if carried out, would put the authorities in possession of many important facts, but there are great difficulties in the way of making such an accurate and full inspection as shall be of practical value in the prevention of an epidemic

SECRETARY OF THE SECTION OF OBSTETRICS AND DISEASES OF WOMEN

The Permanent Secretary of the American Medical Association, in his official notice of the next annual meeting, gives the names and addresses of the officers of the several sections But he gives the residence of Dr J T Jelks, Secreary of the Section of Obstetrics, etc , as Little Rock, when it should be "Hot Springs," Arkansas We make the correction for the benefit of those who may desire to correspond with him regarding the business of that section

PROCEEDINGS OF THE SECTION OF SURGERY AND ANATOMY

Under the head of Society Proceedings, in this number of the JOURNAL, will be found an interesting extract from the official record of the proceedings of this section during the recent meeting in Washington Nearly all the remainder of the record, consisting of the report of discussions on the several papers presented to the section, has been published in connection with the papers to which the discussions referred

SOCIETY PROCEEDINGS

CHICAGO MEDICAL SOCIETY.

Stated meeting March 2, 1885

Mollities Ossium —Dr W J Webb read a paper on this subject, which included a report of a case that he had recently had under his care After some preliminary remarks upon the subject, he stated that he first visited Mr G about the first of August, 1884, and found him lying on his back, with labored respiration Aside from this, all the other external appearances indicated that the patient was comparatively comfortable and well nourished When the bed covering was removed, it was seen that his right arm was bent and fractured, as also were the femora The anterior part of the chest wall was directed forwards and upwards, and as the writer placed his hand over the patient's chest, it imparted a sensation which reminded him of a counting abacus under the skin so nodulated were his ribs There was also a separation of the left supraorbital ridge, which was detached from the continuous bony structure, and upon moving this, crepitus was elicited The detached bone became partially united soon afterwards, as also did a number of other fractures, and remained so until the patient's death The maxillary bones and teeth were quite firm and unyielding The joints of his limbs were slightly enlarged and irregular in outline His appetite was good Temperature 97½° F, respiration 22, pulse 99, accompanied by what was regarded as an aortic heart murmur His bowels were constipated, the tongue slightly coated with a light yellowish fur The amount of urine voided in twenty four hours was 136 ounces, having a specific gravity of 1021, and an acid reaction, with considerable deposit of phosphates, and containing a trace of albumen No microscopial examination was made The patient was partially cyanosed and jaundiced There was also some seborrhœa of the scalp and hairy portions of his body, which was at times accompanied by severe itching This seemed to be due largely to want of proper ablution of the parts Evidence of specific disease, particularly on the anterior portions of his legs, arms, shoulders and upper portions of the chest, were present, as was indicated by a number of characteristic spots and cicatrices His hair was dark and quite normal in other respects, his beard was comparatively thin and confined chiefly to the chin and upper lip The genital organs were atrophied, or diminutive in size

October 6 the following history was elicited His native place was Lycoming county, Pennsylvania He is of German descent, although his parents were born in the United States His father, although always in poor health from "urinary trouble," is living, aged seventy five His mother died at the age of forty-six, cause unknown His father's father died at sixty years of age, his father's mother at nineteen, his mother's father at eighty, mother's mother at fifty five He has a brother living who is in poor health, the result of "heart and lung disease," whose age is thirty one Five sisters are living, the eldest aged forty-five, is an invalid from "liver difficulty," and is unable to do much work, another sister, aged forty-three, is in poor health and suffers from symptoms identical with those of the patient, such as severe aching in her bones, etc The three remaining sisters, aged thirty-nine, thirty-four and thirty, are all living and in poor health About the only vice the patient acknowledges to have indulged in, is that of onanism, which he commenced at the age of eight years and continued moderately during his youth He has always been very passionate in this respect, so much so that it seemed almost impossible for him to satiate himself after he was married This morbid sensation did not forsake him until a few weeks before the writer saw him He stated, also, that he often had quite profuse discharges of milky-looking substance from the penis during defecation, and sometimes before or after voiding his urine, this has troubled him at irregular intervals since his youth At nine years of age he claims to have had a sunstroke, but upon close questioning this was decided to be a fit or convulsion Previous to this he suffered much from indigestion and diarrhœa, and at times passed considerable undigested food After the (so-called) sunstroke he was continually constipated Since the age of sixteen he has been tired and sleepy for a goodly portion of his time, even to lying down and falling asleep in the midst of his work Heavy lifting has always hurt or otherwise injured his bones He has always had a ravenous appetite, in fact, this seemingly abnormal condition was rarely ever satisfied, and besides this he drank a great deal of water, coffee and tea, but has never indulged in alcoholic stimulants

In 1870 or 1871 he moved to Nevada, where he worked in the woods Whilst there he suffered considerably from catarrh and dryness of the throat His appetite continued the same, but at this time he became subject to fits after his meals At the expiration of three months he moved to California, with improved health, though, singularly enough, with an impaired appetite He remained there until 1873, when he returned to Nevada, where he began mining Here he drank a great deal of water that had a sweetish taste, and, as was said of it, contained large quantities of arsenic At this place the patient first noticed an eruption on his skin, which he was told was caused by the arsenic Simultaneously he had sore throat and alopecia After eighteen months he became so badly bloated that he was unable to work He was then seized with an attack of dysentery, which lasted for fully two weeks, the effects of which, he thinks, he never recovered from

In 1875 he resumed "chopping" in the woods but in a short while he was obliged to desist, on account of severe pain in his stomach and in his bones He was also annoyed a great part of the time with a disagreeable taste in his mouth, and by the eruption, which appeared in an aggravated form, besides this, he had numerous furuncles or "blind boils" Further than this, he passed a tapeworm During this year, also, his urine was examined, it was of light specific gravity, and contained albumen In 1876 the patient had a severe struggle with a vicious horse, he then suddenly felt acute shooting pains in numerous portions of his body, and subsequently suffered with diffused soreness and deep-seated pain in both upper and lower extremities This condition remained, with more or less regularity and severity, until the summer of 1882, when he was unable to go about without the aid of crutches In 1877, however, he was married, and has two apparently healthy children, who are 4 and 2 years of age His wife is healthy, but has a prematurely elderly look In 1880 he passed another tapeworm

In 1883 an analysis of his urine showed that it contained albumen, and at one time its measurement reached twelve pounds in twenty-four hours Two weeks before his death a partial chemical analysis of it was made by the writer, and found to contain a peculiar albuminoid substance, which would coagulate when nitric acid was added, but would again redissolve when heat was applied This substance was supposed to be the same as that described by Dr Bence Jones and others as deutoxide of albumen During this long interval of years the patient was treated by a large number of physicians of all faiths for many diseases Some years ago he was salivated, and he thought that the mercury he took was a cause of the pain in his bowels For a year previous to June, 1884, he had taken large quantities of acid phosphates During this month the patient abandoned all attempts at work and took to his bed

On October 6, 1884, the following measurements and other facts in the case were recorded Lower right extremity from symphysis pubis to internal malleolus was 23 inches, lower left extremity measured from the same corresponding points, 26 inches, across the femora, just below the great trochanters, 20 inches, right tibia, 16 inches, left tibia, 17½ inches, sternum, 7 inches The cranial vault was quite easily depressed, and was flexible Total length of his body, 52 inches, original height, 68 inches The pulse was normal, respiration 23 and labored, some ascites was present, appetite good, he sleeps well, mind clear, memory good, his thorax was flattened

October 13 Tongue slightly coated, pulse, 102, temperature, 99° F, respiration, 23 He is otherwise in the same condition, except that both arms are now almost entirely useless

Although a few weeks previously the right humerus had united sufficiently to enable him to use a fan, which afforded him much relief, his thorax continues to flatten, which embarrasses more and more the functions of the respiratory and circulatory organs

October 20 His condition remains much the same as that of one week ago

October 30 Patient's temperature is 97½° F, pulse, 94, quite regular, but soft and weak, his breathing is more labored, and he is considerably cyanosed (The day previously he was thought to be dying, so very dark did he become) The heart's action is exaggerated, with the first sound increased, while the second sound is scarcely audible

November 10 The patient is unable to move any member of his body, except the right hand slightly, and the fingers and toes, his lower extremities are completely everted, and the tissues can be deeply pitted on pressure Temperature is 99° F, pulse, 112, respiration, 24 His appetite remains good, but he vomits his food almost every day, and his sleep is much disturbed by dreams

November 12 Temperature, 99° F, breathing, 25, pulse, 120, with symptoms pointing to giving way of vital forces

November 20 Symptoms improved, temperature, 97½° F, respiration less labored and 22 per minute, pulse, 90 During the past few days his diet has been restricted to raw beefsteak, which has agreed with him, milk causes much distress and provokes vomiting

January 7, 1885 His symptoms of relief were only temporary, at this date he is suffering greatly from dyspnœa The thorax is greatly flattened and the ribs are scarcely perceptible in many places, there is much pain in the right lung, and nearly one-third of it is above the clavicle Temperature not taken, pulse, 115, respiration, 26, and performed with the utmost difficulty There is obstinate constipation There is a small ulcer on his tongue, and an eruption on his face resembling postular acne The copper-colored spots disappeared from his body some weeks ago A cough has set in, and he expectorates a considerable quantity of viscid mucous

During the succeeding two weeks he continued to fail gradually, with all the symptoms more or less intensified, until January 19, when he died of asthenia. His age was about 35 years

An autopsy was made on the following day in the presence of Drs Seiber, Porter and Gates The body was much flattened and diminished in size, so that its general contour much resembled that of the common marsh frog The body was greatly emaciated, and the skeleton was distorted in various ways The entire body and limbs, after being subjected to a stretching process, was 55 inches, left femur, 11 inches, right femur, 11¾ inches, left tibia, 14 inches, right tibia, 13¼ inches, sternum, 6½ inches both humeri, 11 inches, left ulna, 9 inches, right ulna, 10 inches The diaphragm extended on the right side up to the fourth rib, on the left side to a point one and one half inch lower The entire chest-wall, however, was directed upwards at least two inches The heart was in the median line and was moderately distended with blood The pericardium extended up to the second rib, and contained about an ounce of fluid The tissue of both lungs was quite normal in appearance, except that of the upper lobe of the right lung, which was bound down by recent pleuritic adhesions In position they were much crowded upwards, a considerable portion, as has already been stated, was above the clavicle The liver was smaller than normal, and slightly congested The vena cava and pulmonary veins were filled with blood The spleen and pancreas were about one half their normal size, and very pale and tough The kidneys were slightly enlarged, irregular in outline and nodulated Their capsules were thickened, the pyramids were enlarged and the tubules partially filled with what seemed to be a calcareous deposit The pelvis of each kidney contained more fat than is commonly found The bladder was moderately distended, and nearly filled the pelvis The peritoneum, as well as the intestines and stomach, presented an unusually pale and yellowish color The bowels contained hardened feces, the descending colon and the mesenteric glands were enlarged The brain and spinal cord were not exposed, the head, however, was much smaller than formerly, there being at least one and a quarter inch difference in the circumference The entire osseous system was in an abnormal condition The vault of the cranium was as easily depressed as a moderately distended foot-ball, and almost as flexible As was stated in the early portion of this abstract, the bones of the face suffered least, this fact corresponds with most of the other reported cases, yet the maxillary and facial bones were lacking in stability, as was evinced by their being tender to the touch before death, and by the looseness of the teeth, the enamel of the teeth was unaffected The clavicles were enlarged, elongated and much curved upwards and forwards The thorax, as has also been previously stated, resembled that of the frog (*rana palustris*) more than that of a man The sternum was not so much affected as were most of the other bones, this being due, the writer thinks, to the close proximity to the cartilages of the ribs, it was neither in its proper shape nor position, the manubrium, together with the sternal ends of the clavicles, extended upwards and forwards, while the gladiolus pointed upwards and slightly backwards, which made a decided curve posteriorily At the anterior third of the shaft of the ribs, nearly or quite all the proper bone substance was wanting, while the periosteum was bent or folded upon itself The condition of the chest-wall was such as to cause great pressure upon the organs within, and his breathing during the last six months was largely diaphramatic The spinal column, while its natural curves were increased, was enlarged There was quite a sharp and extensive lateral curvature to the right in the dorsal region, and a slight curve to the left in the lumbar region

In the pelvis the distortion was as great as that in the upper part of the body The ossa innominata were nearly at right angles with the horizontal plane of the pelvis The ilia were crowded inwards, while the ischia were directed outwards, the sacrum was directed forwards, and the pubis slightly backwards and downwards This position of the pelvis, together with the lower extremities, including the everted position and the curving outwards of the femora, served to remind one of an old Egyptian lyre, as the outline thus formed was much the shape of the frame of one of these ancient instruments, this description does not apply to the position the body assumed after it was straightened out The upper extremities presented nothing of special importance, except that they were very small, and so soft and flexible that they could easily have been tied in a knot The only specimens of bone removed from the body were the upper half of the right femur with a portion of the acetabulum, the sternum, and a part of a rib Upon the section of the femur, only a trace of bony substance was seen adhering to the inner surface of the periosteum, but as the head of the bone was approached the cancellated structure was more characteristic, though it was not so hard but that it could easily have been incised with an ordinary scalpel When the periosteum was cut into there escaped a considerable quantity of sero-sanguineous fluid that completely enveloped and seemed to permeate the liver-like substance that had taken the place of the medullary canal and the greater part of the shafts of the bones In the trochanters there was an augmentation of soft cancellated substance, containing a large deposit of fat The neck of the bone was shortened, and the great trochanters extended above the articulation with the acetabulum

During the first two months of treatment the patient could not be persuaded to take many remedies, at least in sufficient quantities to produce any perceptible effect, he continued taking acid phosphates and an infusion of senna occasionally to move his bowels, later on he was given iodide of potassium and syrup of sarsaparilla, then a pill of pyrophosphate of iron and quinine The writer suggested that when practicable a water bed should be used for this class of patients, and an ingeniously devised method of effecting moderate extension made of plaster of Paris, or what is probably better, would be some other kind of cast properly adjusted to the chest, might benefit the sufferer This would have a tendency to preserve the proper shape of the thorax, and counteract the contraction of muscles upon which depend the various distortions of the skeleton, and consequently lessen the irritation of sensitive tissues The most positive information that we have as regards this affection has come to us from Europe The valleys of the Rhine and Po seem to furnish the greater number of cases In the female the disease is more often found associated with the pregnant state The social habits and character of the food eaten, where it is deficient in saline constituents of bone, may play an important part in the predisposing cause, also the unsanitary surroundings, added to the character of the water used Rickets, struma, syphilis, miasm, lympho-sarcoma, rheumatism, dampness, hereditary taint, mental disease, etc, were all mentioned as an explanation of the cause of this morbid change The urinary secretion generally presents a marked alteration in character and appearance, and usually contains a deposit of phosphate of lime, which, however, may be a result of tissue metamorphosis According to one of the old writers, osteo-malacia may be divided into three classes (*a*) Those due to carcinomatous or sarcomatous disease of the medulla, (*b*) those due to an affection of the medulla, allied to lymphoma, (*c*) those due to some peculiar condition of the medulla, or perhaps of the blood, dependent on the state of pregnancy

Dr Webb closed by advancing the opinion that in future investigations of this disease, the functions of the nervous system will receive more attention than formerly

Regarding the case reported, the symptoms date prior to the year 1875, when he undoubtedly had syphilis, and since some of the other members of the family have similar symptoms, it is reasonable to infer that a hereditary tendency existed as a predisposing cause This, together with his youthful vice, spermatorrhœa, and erratic temperament, may have been sufficient to induce the albuminuria and a consequent cachexia that served as a fruitful soil for the ravages of the specific disease

Dr C E Webster stated that through the kindness of Dr Webb he had had an opportunity of examining the patient, and was greatly interested in this report of a rare and obscure disease He would like to inquire of the reader if in his study of this disease he had been able to distinctly separate it from the condition known as "fragilitas ossium"

It seemed to him that cases of fragilitas ossium were sometimes diagnosticated as osteo malacia He also thought that there was a tendency, growing from the reticence on the part of patients to admit syphilis, to make that diagnosis in all obscure cases, not giving due credence to other possibilities He would like to know if an examination of the liver was made at the autopsy, and also whether it was an established fact that only a rare form of albumen was soluble in boiling nitric acid Regarding supporting the chest, he thinks no splint could have been devised to prevent collapse of the thorax

Dr J J M Angear spoke of an affection of the trophic nerves as a possible starting point of this disease Regarding onanism as a habit, everything following this practice is of course attributed to it, but he thinks that there is a disease of the trophic nerves that precedes this, or that there is a disease of the nerve centres that causes this depraved condition, and that it is governed by nerve influences He therefore thinks that where a post-mortem examination is made, the nerve centres should be examined in cases in which a patient is known to have practiced onanism, as well as in those having suffered from mollities ossium

Dr A Leich inquired if there were any changes in the small blood-vessels Were they, in conjunction with the portal vein and heart, cyanosed?

Dr Liston H Montgomery thought that if the patient had had syphilis several years previously, and the children were robust in appearance, when during a considerable portion of this time, tertiary symptoms manifested themselves in the father, he could not understand how it was that the children enjoyed good health *now*

Dr Webb closed by stating that he could not answer satisfactorily the questions that had been asked He though there was a close relation between some cases of mollities ossium and fragilitas ossium, rickets and specific disease Regarding the nerve centres that control the process of nutrition, he thinks it is quite probable that they are first the seat of the disease, or that hydro-myelitis or osteo-myelitis may be complicated with it He was sorry that he had not closely examined the liver in this case, and obtained slides for microscopical examinations

EXTRACT FROM THE SECOND DAY'S PROCEEDINGS OF THE SECTION OF SURGERY AND ANATOMY, IN WASHINGTON, D C, MAY 7, 1884

Dr L A Sayre, of New York, read the report of the committee appointed relative to the death of Dr S D Gross

Resolved, That the members of the Section of Surgery and Anatomy of the American Medical Association have received with a sense of profound regret the intelligence of the death of Prof Samuel D Gross, M D, of the State of Pennsylvania, one of the greatest ornaments of this Association, and one of the most distinguished teachers and authors in the medical profession in the United States

Resolved, That the memory of the deceased deserves to be cherished with love and veneration by the members of the medical profession, as that of a man profoundly versed in medical science and worthy to be ranked with the greatest and ablest of our age and country

He had mastered the vast learning of his profession, and the natural kindness of his great and generous heart was such that, throughout his long and successful career as a practitioner, he was continually experiencing the most intense satisfaction and pleasure in relieving by his science the suffering of humanity

Resolved, That these resolutions be entered upon the journal of the proceedings of this section, and that the chairman transmit a copy to the family of the deceased J M Kellar, Ch'n

Lewis A Sayre, Austin Flint, Jr, R A Kinloch

On motion, the resolutions were adopted

Dr J W S Gouley, of New York, by consent of the section, presented a specimen of "*Spontaneous Fracture of Vesical Calculus*," with the following history The specimen was from a patient 79 years of age, who had been under treatment a year or two for urinary trouble The patient first came under the care of Dr Dexter, of Washington, D C Suspecting that there might be stone in the bladder, he proceeded to gradually dilate the urethra with the view of subsequently evacuating it After four or five weeks of this treatment the patient suddenly passed several fragments of stone, eighteen or twenty in number Ten or twelve of these Dr Gouley now exhibited to the section Other fragments were passed at various times Afterwards there was a partial removal by Bigelow's apparatus, and subsequently cystotomy performed, when the patient died

The fragments were smooth, not water worn, and gave positive evidence, from their appearance, of fracture several months before their evacuation How did this happen? No authentic record of such cases is given He thought that the cause of fracture in this case was first erosion at some point, and afterward a sudden fragmentation of the stone

Dr Gouley's explanation of this mode of fracture is similar to what takes place in Prince Rupert's pearl, when eroded

Dr L A Sayre, of New York, did not think it possible for a stone to fracture spontaneously in the bladder, and asked if it had not been previously examined to determine its size, and if it were broken

Dr Thompson, of Washington, D C, had previously attended this patient, and had attempted to remove the stone by Bigelow's method, but failed He resorted to lithotomy, when the patient died in a few hours

The bladder of this patient was contracted to the size of a walnut, and in his opinion the fracture was due to contraction of the bladder and was not a spontaneous fracture

Dr Hutchinson, of New York, reported in this connection the removal of a mulberry calculus from a young man, which measured in length 1¾ inches and ¾ inch in diameter, presenting a complete fracture through its center, which had undoubtedly broken spontaneously No instruments had been used previously, nor was there any evidence of abrasion

Dr Prewitt, of Missouri, was of the opinion that the fracture in this case was due to contraction, as the stone was soft He did not think that Dr Gouley's theory would hold good

Dr Pollock, of Pennsylvania, reported the removal of 66 triangular shaped stones, weighing in all five ounces It did not occur to him that there had been any fracture in the bladder in this case, yet it might have been

Dr Dawson, of Ohio, thought that the stone must have been broken by the previous use of instruments, and could not think that there was sufficient force in the contraction of the bladder to fracture a stone, however soft it might be He had once removed a mulberry calculus larger than a hen's egg, that had never given much trouble previous to removal

STATE MEDICINE

A BILL FOR AN ACT TO PROVIDE FOR THE COMMITMENT OF THE INSANE *

Be it enacted—First, That the judges of the courts of each judicial district shall, jointly, nominate to the governor, within sixty days next after the passage of this act, two physicians in each county best qualified to act as Commissioners of Insanity

Second, That the governor, within thirty days next after the reception of such nomination, shall appoint the said two physicians to be Commissioners of Insanity in and for each of said counties respectively

Third, That the said two commissioners so appointed, together with the judge of the county court, in and for each of said counties, respectively, constitute the Board of Commissioners of Insanity for said county

Fourth, That the said Board of Commissioners have exclusive and complete jurisdiction of all matters pertaining to the commitment and custody of the insane, and power and authority adequate to the determination thereof

Fifth, That affidavit of alleged insanity be made to the clerk of the county — ex officio clerk to the Board of Commissioners of Insanity — to be reported by him to the judge of the county court — ex-officio president of the said board — within twenty-four hours of the date of the said affidavit

Sixth, That the alleged insane person be examined by each and all of the said commissioners, privately, publicly, separately or jointly, as may be deemed, by each, necessary to the determination of the truth

Seventh, That insanity be determined only by unanimous decision of the said Board

Eighth, That, in case of disagreement, the minority may demand, and the Board must grant, a re-examination

Ninth, That the said Board, having determined the insanity of any one, shall order his (or her) commitment, if curable, to a State hospital for the insane, if incurable, to a county asylum, or to such other custody as may seem best adapted to the circumstances of any special case

Tenth, That each of said Commissioners, so appointed, receive the sum of —— dollars for each and every case of alleged insanity examined by him, and in addition thereto the sum of —— —— for each and every mile necessarily traveled by him to and from the places of holding said examination, the same to be paid as fees to jurors hitherto

Eleventh, That the term of service of one of said Commissioners, so appointed, be three years, to be determined by lot, that of all others to be five years —in order that a majority of said Board may always consist of old members

Provided, That nothing in this Act shall be construed to prevent the trial by jury, as at present, of any alleged insane person who may, either personally or by his or her friends, elect that mode of examination, and that for all such cases the statutes now in force shall continue effective

HEALTH IN MICHIGAN, FEBRUARY, 1885.

Reports to the State Board of Health, Lansing, by regular observers in different parts of the state, show the diseases which caused most sickness in Michigan during the month of February (four weeks ending February 28), 1885, as follows

Number of weekly reports received, 152		*For preceding month*
Diseases arranged in order of greatest prevalence	*Per cent of reports stating presence of disease*	*Per cent of reports stating presence of disease*
Neuralgia	80	82
Bronchitis	74	74
Rheumatism	72	75
Consumption of lungs	63	61
Influenza	61	60
Pneumonia	59	46
Tonsilitis	57	65
Fever, intermittent	47	50
Erysipelas	37	37
Diarrhœa	31	26
Inflammation of kidney	30	22
Intermittent fever	29	50
Inflammation of bowels	15	16
Scarlet fever	15	16
Whooping cough	15	18
Cerebro spinal meningitis	11	11
Diphtheria	11	16
Typho malarial fever	11	13
Membranous croup	10	14
Typhoid fever (enteric)	8	11
Measles	7	4
Inflammation of brain	6	9
Dysentery	6	6
Cholera morbus	5	5
Puerperal fever	5	4
Cholera infantum	3	2
Small pox	0 7	0

---

[*] This form of a bill was proposed by a committee consisting of Drs Walter Hay Wm Hill, and E P Cook and approved by the Illinois State Medical Society in annual meeting, May 1883

For the month of February, 1885, compared with preceding month, the reports indicate that pneumonia and inflammation of kidney increased, and that intermittent fever and tonsilitis decreased in prevalence.

Compared with the average for the month of February in the seven years, 1879–1885, erysipelas and neuralgia were more prevalent, and intermittent fever, diphtheria, remittent fever, measles and scarlet fever, were less prevalent in February, 1885.

For the month of February, 1885, compared with the average of corresponding months for the seven years, 1879–1885, the temperature was considerably lower, the absolute humidity and the day and the night ozones were less, and the relative humidity was more.

Including reports by regular observers and others, diphtheria was reported in Michigan in the month of February, 1885, at thirty-six places, namely: Albion, Alcona, Cadillac, Cedar Springs, Dexter, Detroit, East Saginaw, Grand Rapids, Harrisville, Holly, Hope tp., Ishpeming, Ithaca, Ingham tp., Kalamazoo, Leelanaw, Lexington, Marquette, Maple Valley, Muskegon, Muskegon tp., New Haven tp., North Star, Novi tp., North Muskegon, Otsego, Oshtemo, Oshtemo tp., Owosso, Pierson, Pierson tp., Port Crescent, South Bay City, Taylor, Winfield, Wyandotte. Scarlet fever at twenty-eight places: Adrian, Albion, Berlin tp., Burchville, Chester, Charlevoix, Detroit, Dover, Dundee, East Saginaw, East Tawas, Forest tp., Grand Haven, Grand Rapids, Homer, Kalamazoo, Kearney, Leelanaw tp., Lowell, Linden, Manistee, North Muskegon, Novi, Pentwater, Power tp., Pierson, Sheriden tp., South Haven, Vernon tp. Measles at East Saginaw, Detroit, Grand Rapids, Hopkins tp., and small-pox at East Saginaw and South Boardman.

HENRY B. BAKER, *Secretary.*

Lansing, Michigan, March 5, 1885.

FOREIGN CORRESPONDENCE

BERLIN LETTER

BERLIN, Feb. 24, 1885.

The Abdominal Surgery of Dr. A. Martin—Parametritis and Perimetritis—Cocaine in Reflex Neurosis—Litholapaxie—Emmet's Operation—The Lepra Bacillus and Bacilli in General.—The results of Dr. A. Martin's abdominal surgery, under the strictest antiseptic precautions are as follows: He has extirpated the kidney eleven times with four deaths; 105 ovariotomies with four deaths, one only being from sepsis. Out of sixty laparotomies thirty-one were healed without drainage, and twenty-nine with drainage. Of the thirty-one cases without drainage the mortality was 35.5 per cent., seven deaths being from sepsis. Of the twenty-nine cases treated with drainage the mortality was 24.2 per cent., four deaths being from sepsis. He operated the other day in a case of tubal pregnancy of exceptional interest. The patient was well on to six months, and the whole cyst was excised without rupturing the sac, the fœtal left foot alone protruding. It has been the fashion for many years among German gynæcologists to draw a sharp line of demarcation between *parametritis and perimetritis*, a custom which, happily, is now falling into desuetude. Emmet, practically, stated a far reaching truth in the last edition of his book, in refusing any clinical credence to this differential terminology. The theory of two distinct inflammations of the para-metrium and the perimetrium is not a sound pathological one, and is a very unsound clinical one. In a very popular little handbook, by C. G. Rothe on the disease of women, in high favor among German students, the author admits that there is no clinical distinction whatever, and that the treatment is the same in both cases. The most acute diagnostician will find it difficult to relegate the inflammation to the *cavum pelvis peritoneale*, or to the *cavum pelvis subperitoneale*, and for the matter if that, so far as the comfort and well being of the patient may be concerned, it does not make a particle of difference which peritoneale space is made to suffer. I am glad that one who is recognized as a leader has had the courage to raise his voice against such a meaningless multiplicity of terms. To all intents and purposes the entire profession accepted this view of the case years ago, when they adopted Emmet's treatment by hot water injections. Cocaine, in every possible aspect, was discussed to exhaustion, in the meeting of the medical society here January 14. At the previous meeting papers upon cocaine having been read by Dr. Heymann and by Dr. Schweigger, it was shown to act decidedly upon the sympathetic nerve, and to reduce the amount of blood sent to the part to which it was applied. With this in mind, it was found to be a valuable agent in reflex neuroses, with difficult breathing, such as asthma, etc. In hay asthma, the membrane over the turbinated bones is highly engorged with blood, and the peripheral terminations of the nerves are irritated by pressure—a local application will relieve all the symptoms for twelve hours or more. That it does diminish the amount of blood sent to a given part, is clearly shown in an iridectomy under an application of cocaine. If this remedy, locally applied, shall serve to relieve the severe spasms of hay asthma, its value can never be measured or estimated. At a meeting of the medical society, January 14 and on January 21, the operation of litholapaxy was very thoroughly reviewed and discussed. Dr. Furstenheim read a paper on a case of litholapaxy, opening with a history of the operations of Civiale, Heurteloup, Thompson, Bigelow and Otis, and going back into the times of Franco von Lausanne, von Pasquier, Gruithuisen and Cornay. He reviewed the discussions at the International Congresses of 1879 and 1881, and also quoted the remarks of Volkmann and Bergmann before the surgical section of Magdeburg: "Dass die Lithotripsie und Litholapaxie Methoden seien, welche in unsere aseptische Zeit uberhaupt nicht mehr hineinpassten." He approved the operation and recommended it highly. In the discussion that followed (full account can be seen in Nos. 6 and 7, Berliner
